Data Supplement 45. RCTs and Meta-analysis Comparing PAD (Section 9.5) .......................................................................................................................................................... 168
Data Supplement 46. RCTs and Meta-analyses Comparing BP Targets in DM (Section 9.6) .......................................................................................................................................................... 174
Data Supplement 47. Nonrandomized Trials, Observational Studies, and/or Registries in DM (Section 9.6) .......................................................................................................................................................... 183
Data Supplement 48. Atrial Fibrillation (Section 9.8) .......................................................................................................................................................... 190
Data Supplement 49. Valvular Heart Disease (Section 9.9) .......................................................................................................................................................... 191
Data Supplement 50. RCTs and Meta-analysis Comparing Valvular Heart Disease (Section 9.9) .......................................................................................................................................................... 194
Data Supplement 51. RCTs Comparing Race/Ethnicity (Section 10.1) .......................................................................................................................................................... 197
Data Supplement 52. RCTs Comparing Women With Hypertension (Section 10.2.1) .......................................................................................................................................................... 201
Data Supplement 53. RCTs Comparing Pregnancy (Section 10.2.2) .......................................................................................................................................................... 203
Data Supplement 54. RCT for Older Persons (Section 10.3.1) .......................................................................................................................................................... 204
Data Supplement 55. RCTs Comparing Hypertensive Crises and Emergencies (Section 11.2) .......................................................................................................................................................... 204
Data Supplement 56. RCTs Assessing Impact of Hypertension Therapy on Dementia Incidence (Section 11.3) .......................................................................................................................................................... 207
Data Supplement 57. RCTs for Patients Undergoing Surgical Procedures (Section 11.5) .......................................................................................................................................................... 210
Data Supplement 58. Observational and Nonrandomized Studies for Patients Undergoing Surgical Procedures (Section 11.5) .......................................................................................................................................................... 211
Data Supplement 59. RCTs of Adherence and Compliance with Fixed Dose Combinations Regimens (Section 12.1.1) .......................................................................................................................................................... 213
Data Supplement 60. Nonrandomized Trials, Observational Studies, and/or Registries of Antihypertensive Medication Adherence Strategies (Section 12.1.1) .......................................................................................................................................................... 214
Data Supplement 61. RCTs and Meta-analysis on Strategies to Promote Lifestyle Modification (Section 12.1.2) .......................................................................................................................................................... 220
Data Supplement 62. RCTs, Meta-analyses, and Systematic Reviews on the Effect of Structured, Team-based Care Interventions for Hypertension Control (Section 12.2) .......................................................................................................................................................... 221
Data Supplement 63. Electronic Health Records and Patient Registries (Section 12.3.1) .......................................................................................................................................................... 227
Data Supplement 64. RCTs, Meta-analyses, and Systematic Reviews on the Effect of Telehealth Interventions to Improve Hypertension Control (Section 12.3.2) .......................................................................................................................................................... 232
Data Supplement 65. RCTs and Observational Studies that Report on the Effect of Performance Measures and on Hypertension Control (Section 12.4.1) .......................................................................................................................................................... 236
Data Supplement 66. RCTs, Meta-analyses, and Systematic Reviews on Quality Improvement Strategies on Hypertension Treatment Outcomes (Section 12.4.2) .......................................................................................................................................................... 238
Data Supplement 67. Nonrandomized Trials, Observational Studies, and/or Registries of Effect of Quality Improvement Strategies on Hypertension Treatment Outcomes (Section 12.4.2) .......................................................................................................................................................... 244
Data Supplement 68. RCTs Comparing Financial Incentives (Section 12.5) .......................................................................................................................................................... 245
Additional Data Supplement Tables and Figures .......................................................................................................................................................... 252
Search Terms:

An extensive evidence review, which included literature derived from research involving human subjects, published in English, and indexed in MEDLINE (through PubMed), EMBASE, the Cochrane Library, the Agency for Healthcare Research and Quality, and other selected databases relevant to this guideline, was conducted between February and August 2015. Key search words included but were not limited to the following: adherence; aerobic; alcohol intake; ambulatory care; antihypertensive: agents, drug, medication, therapy; beta adrenergic blockers; blood pressure: arterial, control, determination, devices, goal, high, improve, measurement, monitoring, ambulatory; calcium channel blockers; diet; diuretic agent; drug therapy; heart failure: diastolic, systolic; hypertension: white coat, masked, ambulatory, isolated ambulatory, isolated clinic, diagnosis, reverse white coat, prevention, therapy, treatment, control; intervention; lifestyle: measures, modification; office visits; patient outcome; performance measures; physical activity; potassium intake; protein intake; renin inhibitor; risk reduction: behavior, counseling; screening; sphygmomanometers; spironolactone; therapy; treatment: adherence, compliance, efficacy, outcome, protocol, regimen; weight. Additional relevant studies published through June 2016, during the guideline writing process, were also considered by the writing committee, and added to the evidence tables when appropriate.
2017 Hypertension Guideline Data Supplements

**Abbreviations:**

1st, primary; 2nd, secondary; AASK, African American Study of Kidney Disease and Hypertension; ABI, ankle-brachial index; ABCD, Appropriate Blood Pressure Control in Diabetes; ABPM, ambulatory blood pressure monitoring; ACCESS, Acute Candesartan Cilexetil Evaluation in Stroke Survivors; ACCOMPLISH, Avoiding Cardiovascular Events Through Combination Therapy in Patients Living With Systolic Hypertension; ACCORD, Action to Control Cardiovascular Risk in Diabetes; ACE, angiotensin-converting enzyme; ACEI, angiotensin-converting enzyme inhibitor; ACS, acute coronary syndrome; ADVANCE, Action in Diabetes and Vascular Disease; AF, atrial fibrillation; AFL, atrial flutter; AHR, adjusted hazard ratio; AIPRD, Angiotensin-Converting Enzyme Inhibition in Progressive Renal Disease; ALLHAT, Antihypertensive Lipid Lowering Treatment to Prevent Heart Attack Trial; AMI, acute myocardial infarction; ARB, angiotensin-receptor blocker; ARIC, Atherosclerosis Risk in Communities; ASCOT, Anglo-Scandinavian Cardiac Outcomes Trial; BB, beta blocker; BMI, body mass index; BP, blood pressure; BPLTTC, Blood Pressure Lowering Treatment Trialists’ Collaboration; bpm, beats per minute; BUN, blood urea nitrogen; CABB, coronary artery bypass graft; CAD, coronary artery disease; CATIS, China Antihypertensive Trial in Acute Ischemic Stroke; CCB, calcium-channel blocker; CCU, coronary care unit; CHD, coronary heart disease; CHF, congestive heart failure; CHHIPS, Controlling Hypertension and Hypotension Immediately Post-Stroke; CI, confidence interval; CKD, chronic kidney disease; COMFORT, Combination Pill of Losartan Potassium and Hydrochlorothiazide for Improvement of Mediation Compliance Trial; COSSACS, the Continue or Stop Post-Stroke Antihypertensives Collaborative Study; CPAP, continuous positive airway pressure; Cr, creatinine; CrCl, creatinine clearance; CRP, c-reactive protein; CR/XL, metoprolol controlled release/extended release; CT, computed tomography; CV, cardiovascular; CVD, cardiovascular disease; DASH, Dietary Approaches to Stop Hypertension; DBP, diastolic blood pressure; DM, diabetes mellitus; DM-1, diabetes mellitus type-1; DM-2, diabetes mellitus type-2; ECG, electrocardiogram; ED, emergency department; EF, ejection fraction; eGFR, estimated glomerular filtration rate; ESKD, end-stage kidney disease; ESRD, end-stage renal disease; FC, functional class; FDC, fixed dose combination; FEVER, Felodipine EVent Reduction; GITs, gastrointestinal therapeutic system; GFR, glomerular filtration rate; HBPM, home blood pressure monitoring; HCTZ, hydrochlorothiazide; HDL, high-density lipoprotein; HDL-C, high-density lipoprotein cholesterol; HEDIS, Healthcare Effectiveness Data and Information Set; HF, heart failure; HFrEF, reduced ejection fraction; HfPcEF, heart failure with preserved ejection fraction; HIV, human immunodeficiency virus; HR, hazard ratio; HTN, hypertension; ICD, implantable cardioverter-defibrillator; ICH, intracerebral hemorrhage; IDACO, International Database of Ambulatory Blood Pressure in relation to Cardiovascular Outcome; IHD, ischemic heart disease; IMT, intimal media thickness; INDANA, Individual Data Analysis of Antihypertensive drug intervention trials; INTERACT2, the second intensive Blood Pressure Reduction in Acute Cerebral Hemorrhage Trial; INVEST, International Verapamil-Trandolapril Study; INWEST, the Intravenous Nimodipine West European Stroke Trial; IQI, interquartile interval; IQR, interquartile range; IRR, incident rate ratio; ISDN, isosorbide dinitrate; IV, intravenous; JNC-7, 7th Report of the Joint National Committee; KPNC, Kaiser Permanente Northern California; LDL, low-density lipoprotein; LGSAS, low-gradient severe aortic stenosis; LIFE, Losartan Intervention For Endpoint Reduction in Hypertension; LVEF, left ventricular ejection fraction; LVH, left ventricular hypertrophy; LVMI, left ventricular mass index; MACCE, major adverse cardiac and cerebrovascular events; MACE, major adverse cardiac events; MAP, mean arterial pressure; MD, mean difference; MDPIT, Multicenter Dilitiazem Postinfarction Research Group; MDRD, Modification of Diet in Renal Disease; MERIT, Metoprolol CR/XL Randomised Intervention Trial; MESA, Multi-Ethnic Study of Atherosclerosis; MH, masked hypertension; MI, myocardial infarction; MOSES, The Morbidity and Mortality After Stroke, Eprosartan Compared With Nitrendipine for Secondary Prevention; MPR, medication possession ratio; MRFIT, Multiple Risk Factor Intervention Trial; MRI, magnetic resonance imaging; N/A, not available; NCQA, National Committee for Quality Assurance; NEMESIS, North East Melbourne Stroke Incidence Study; NHANES, National Health and Nutrition Examination Surveys; NIH, National Institute of Health; NNT, number needed to treat; NR, not relative;
NS, nonsignificant; NSAID, nonsteroidal anti-inflammatory drug; NUTRICODE, Nutrition and Chronic Diseases Expert Group; NYHA, New York Heart Association; ONTARGET, Ongoing Telmisartan Alone and in Combination With Ramipril Global Endpoint Trial; OR, odds ratio; OSA, obstructive sleep apnea; P4P, pay for performance; PA, pulmonary artery; PAD, peripheral artery disease; PAMELA, Pressione Arteriose Monitorate E Loro Associazioni; PCP, primary care provider; periop, perioperative; PREDIMED, Prevention with a Mediterranean Diet; PRISMA, Preferred Reporting Items for Systematic Reviews and Meta-Analyses; PROBE, Prospective, randomized, open, blinded endpoint; PROGRESS, The perindopril protection against recurrent stroke study; PRONTO, Prospective Optical Coherence Tomography Imaging of Patients with endovascular Age-Related Macular Degeneration Treated with Intraocular Ranibizumab; pt, patient; PTCA, percutaneous transluminal coronary angioplasty; PVD, peripheral vascular disease; QI, quality improvement; RAAS, renin angiotensin aldosterone system; RCT, randomized controlled trial; REIN-2, Blood Pressure Control for Renoprotection in Patients with Non-diabetic Renal Disease; RH, relative hazard; ROADMAP, Randomized Olmesartan and Diabetes Microalbuminuria Prevention; RR, relative risk; Rx, medical prescription; SAE, severe adverse event; SBP, systolic blood pressure; SCOPE-AS, Symptomatic Cardiac Obstruction – Pilot Study of Enalapril in Aortic Stenosis; SD, standard deviation; SE, stress echocardiography; SH, sustained hypertension; SHEP, Summer Health Enrichment; SITS-ISTR, Safe Implementation of Thrombolysis in Stroke-International Stroke Thrombolysis Register; SKIPOGH, Swiss Kidney Project on Genes in Hypertension; SPC, single pill combination; SPRINT, Systolic Blood Pressure Intervention Trial; Syst-Eur, Systolic Hypertension in Europe; t-PA, tissue plasminogen activator; TIA, transient ischemic attack; TOHP, Trials of Hypertension Prevention; TOMHS, Treatment of Mild Hypertension Study; TONE, Trial of Nonpharmacologic Intervention in the Elderly; TOPCAT, Treatment of Preserved Cardiac Function Heart Failure With Aldosterone Antagonist; TR, target range; UA, unstable angina; U.K., United Kingdom; UKPDS, United Kingdom Prospective Diabetes Study; U.S., United States; VA, Veterans Affairs; VA Coop; Veterans Administration Cooperative Study Group on Antihypertensive Agents; VA NEPHRON-D, Veterans Affairs Nephropathy in Diabetes; VALIANT, Valsartan in Acute Myocardial Infarction Trial; VALUE, Valsartan Antihypertensive Long-term Use Evaluation; WCH, white coat hypertension; and WPW; Wolff-Parkinson-White syndrome.

| Wilson PW, et al., 1999 (1) 10335688 | **Study type:** Nonrandomized  
**Size:** 2,406 men, 2,569 women (1,759 men, 1,818 women with follow-up)  
**Inclusion criteria:** Men and women 18–74 y and free of CHD at baseline, from the Framingham Offspring Study  
**Exclusion criteria:** N/A | 1° endpoint: Total CHD (first occurrence of angina, UA, MI, and coronary death), Hard CHD (first MI and coronary death)  
**Results:** Presence of ≥3 risk factors associated with a 2.39 times greater risk of CHD in men (95% CI: 1.56–3.36; p<0.001) and a 5.90 increased risk of CHD in women (95% CI: 2.54–13.73; p<0.001) | • CVD risk factors infrequently occur in isolation (only 28%–30% of the time); presence of ≥3 risk factors occurred 17% of the time in both men and women; presence of ≥3 risk factors associated with high risk of CHD and coronary death (attributable risk of 20% in men and 48% in women) |
| Berry JD, et al., 2012 (2) 22276822 | **Study type:** Nonrandomized  
**Size:** 257,384 black and white men and women, including 67,890 pts (from 17 meta-analysis) and 189,494 pts (from MRFIT)  
**Inclusion criteria:** Meta-analysis of 18 cohort studies  
**Exclusion criteria:** N/A | 1° endpoint: Fatal CHD, nonfatal MI, fatal or nonfatal stroke  
**Results:** Participants with optimal RF profile (total cholesterol <180 mg/dL, untreated BP <120 mm Hg systolic, and <80 mm Hg diastolic, nondiabetic, nonsmoker) compared to participants with ≥2 risk factors had lower risk of CVD through the age of 80 y (4.7% vs. 29.6% for men, 6.4% vs. 20.5% for women), lower lifetime risk of fatal heart disease and nonfatal MI (3.6% vs. 37.5% for men, <1% vs. 18.3% for women), and lower lifetime risk of fatal or nonfatal stroke (2.3% vs. 8.3% for men, 5.3% vs. 10.7% for women) | • Increased burden of 80 risk factors associated with higher lifetime risk of CVD |
### Data Supplement 2. Definition of High BP (Section 3.1)

<tr>
<td>Lewington S, et al., 2002 12493255</td>
<td>Study type: Meta-analysis of 61 observational cohort studies</td>
<td>Inclusion criteria: Men and women with no history of previous CVD and record of key study variables. Exclusion criteria: Prior CVD</td>
<td>1º endpoint: Cause-specific mortality Results: 958,074 persons followed for a mean of 12 y to death (12.7 million person-y at risk. Number of deaths attributed to: -Stroke: 11960 -IHD: 34,283 -Other vascular:10092 -Non-vascular: 60797 Above a SBP ≥115 mm Hg and DBP ≥75 mm Hg, there was a progressive rise in vascular death with progressively high BP with no evidence of a J-curve (approximately doubling of stroke and IHD mortality for a 20 mm Hg higher level of SBP or 10 mm Hg higher level of DBP, in those 40–69 y). With progressively higher age, the BP-related proportional risk of vascular mortality was somewhat reduced but the corresponding absolute risk was much higher.</td>
<td>• In adults aged 40–89 y, usual BP is strongly related to vascular (and overall) mortality, without evidence of a threshold down to at least an SBP/DBP of 115/75 mm Hg.</td>
</tr>
<tr>
<td>Rapsomaniki E, et al., 2014 24881994</td>
<td>Study type: Observational cohort study Size: 1.25 million patients, in 225 primary care practices in the UK, followed for a median of 5.2 y using electronic medical records.</td>
<td>Inclusion criteria: Men and women ≥30 y, with no previous diagnosis of CVD, who had been registered at their practices for ≥1 year. Exclusion criteria: N/A</td>
<td>1º endpoint: 12 acute and chronic CVD outcomes Results: 83,098 initial CVD events recorded. Within each of 3 age groups (30–59, 60–79, and ≥80 y), the lowest risk for CVD was in those with a SBP 90–114 mm Hg and DBP 60–74 mm Hg. There was a direct relationship between level of BP and most CVD outcomes, with no evidence of J-curve, with the strongest relationship for SBP and stroke and weakest for abdominal aneurysm.</td>
<td>• Despite modern treatments, the lifetime burden of BP-related CVD was substantial.</td>
</tr>
<tr>
<td>Wilson PW, et al., 1999 (1) 10335688</td>
<td>Study type: Nonrandomized Inclusion criteria: Men and women 18–74 y and free of CHD at baseline, from the Framingham Offspring Study</td>
<td>1º endpoint: Total CHD (first occurrence of angina, UA, MI, and coronary death), Hard CHD (first MI and coronary death)</td>
<td>CVD risk factors infrequently occur in isolation (only 28%–30% of the time)</td>
<td></td>
</tr>
</tbody>
</table>
### Study type: Meta-analysis of nonrandomized studies

#### Size: 2,406 men, 2,569 women (1,759 men, 1,818 women with follow-up)

**Exclusion criteria:** N/A

#### Results: Presence of ≥3 risk factors was associated with a 2.39 times greater risk of CHD in men (95% CI: 1.56–3.36; p<0.001) and a 5.90 increased risk of CHD in women (95% CI: 2.54–13.73; p<0.001)

- Presence of ≥3 risk factors occurred 17% of the time in both men and women
- Presence of ≥3 risk factors associated with high risk of CHD and coronary death (attributable risk of 20% in men and 48% in women)

---

### Study type: Meta-analysis of nonrandomized studies

#### Size: 870,678 pts

**Inclusion criteria:** Studies reporting adjusted risk for CVD or mortality with pre-HTN

**Exclusion criteria:** N/A

#### 1° endpoint: CVD and all-cause mortality

#### Results: SBP/DBP 120–129/80–84 mm Hg compared to <120/80 mm Hg:
- All-cause mortality: RR: 0.91; 95% CI: 0.81–1.02
- CVD mortality: RR: 1.10 (95% CI: 0.92, 1.30)
  - SBP/DBP 130–139/85–89 mm Hg compared to <120/80 mm Hg:
    - All-cause mortality: 1.00; 95% CI: 0.95–1.06
    - CVD mortality: RR: 1.26; 95% CI: 1.13–1.41

- Compared to pts with SBP/DBP <120/80 mm Hg, the RR for CVD, MI and stroke were larger for pts with SBP/DBP of 130–139/85–89 mm Hg vs. SBP/DBP of 120–129/80–84 mm Hg.

---

### Study type: Meta-analysis of nonrandomized studies

#### Size: 1,010,858 pts

**Inclusion criteria:** Studies reporting adjusted risk for fatal and nonfatal stroke, CHD, MI and total CVD events with pre-HTN, 120–129/80–84 mm Hg or 130–139/85–89 mm Hg

**Exclusion criteria:** N/A

#### 1° endpoint: Fatal and nonfatal stroke, CHD, MI and total CVD events

#### Results: SBP/DBP 120–129/80–84 mm Hg compared to <120/80 mm Hg:
- CVD RR: 1.24; 95% CI: 1.10–1.39
- MI RR: 1.43; 95% CI: 1.10–1.86
- Stroke RR: 1.35; 95% CI: 1.10–1.66
  - SBP/DBP 130–139/85–89 mm Hg compared to <120/80 mm Hg:
    - CVD RR: 1.56; 95% CI: 1.36–1.78
    - MI RR: 1.99; 95% CI: 1.59–2.50
    - Stroke RR: 1.95; 95% CI: 1.69–2.24

- Compared to pts with SBP/DBP <120/80 mm Hg, the RR for CVD, MI and stroke were larger for pts with SBP/DBP of 130–139/85–89 mm Hg vs. SBP/DBP of 120–129/80–84 mm Hg.

---

### Study type: Meta-analysis of nonrandomized studies

#### Size: 468,561 pts from 18 prospective cohort studies

**Inclusion criteria:** Studies reporting risk for CVD, CHD and stroke, with 120–139/80–89 mm Hg

- Adults ≥18 y BP evaluated at baseline

#### 1° endpoint: CVD, CHD, and stroke

#### Results: Comparing SBP/DBP 120–129/80–84 mm Hg to <120/80 mm Hg:
- CVD RR: 1.46; 95% CI: 1.32–1.62
### Study 1: ESRD

**Huang Y, et al., 2014 (6)**

**Study type:** Meta-analysis of nonrandomized studies

**Size:** 1,003,793 pts were derived from 6 prospective cohort studies

**Inclusion criteria:** Studies reporting adjusted risk for ESRD with 120–139/80–89 mm Hg, 120–129/80–84 mm Hg or 130–139/85–89 mm Hg

**Exclusion criteria:**
- 1) enrollment depended on having a condition or risk factor
- 2) the study reported only age- and sex-adjusted RRs
- 3) data were derived from the same cohort or from a meta-analysis

**1° endpoint:** ESRD

**Results:** Comparing SBP/DBP 120–129/80–84 mm Hg to <120/80 mm Hg:
- ESRD RR: 1.44; 95% CI: 1.19–1.74

Comparing SBP/DBP 130–139/85–89 mm Hg to <120/80 mm Hg:
- ESRD RR: 2.02; 95% CI: 1.70–2.40;

*p value comparing these risk ratios = 0.01*

### Study 2: Stroke

**Huang Y, et al., 2013 (7)**

**Study type:** Meta-analysis of nonrandomized studies

**Size:** 762,393 pts from 19 prospective cohort studies

**Inclusion criteria:** Studies reporting adjusted risk for stroke with 120–139/80–89 mm Hg, 120–129/80-84 mm Hg or 130–139/85–89 mm Hg

**Exclusion criteria:**
- Enrollment depended on having a specific risk factor condition (e.g., DM or other baseline chronic diseases)
- The RR was unadjusted or only adjusted for age and sex
- Data were derived from the same cohort or meta-analysis of other cohort studies.

**1° endpoint:** Stroke

**Results:** Comparing SBP/DBP 120–129/80–84 mm Hg to <120/80 mm Hg:
- Stroke: RR: 1.44; 95% CI: 1.27–1.63

Comparing SBP/DBP 130–139/85–89 mm Hg to <120/80 mm Hg:
- Stroke: RR: 1.95; 95% CI: 1.73–2.11

*p value comparing these risk ratios ≤ 0.001*

Size: 518,520 pts from 18 prospective cohort studies

- BP evaluated at baseline
- Results reported with adjustment

**Exclusion criteria:**
- Cross-sectional, case-control or retrospective cohort
- The RR was unadjusted or only adjusted for age and sex
- 95% CI not reported
- Data were derived from the same cohort or meta-analysis of other cohort studies
- Results from trial of antihypertensive medication

Comparing SBP/DBP 130–139/85–89 mm Hg to <120/80 mm Hg:
- Stroke RR: 1.79; 95% CI: 1.49–2.16

<td>2° analysis of an RCT</td>
<td>33,357 pts in the ALLHAT</td>
<td>Men and women ≥55 y with HTN and 1 additional CHD risk factor Pts randomized to doxazosin.</td>
<td>Achieving SBP/DBP&lt;140/90 mm Hg, use of ≥2 drug classes</td>
<td>BP control (&lt;140/90 mm Hg) can be achieved in most pts ≥2 or more drug classes are often required.</td>
</tr>
</tbody>
</table>
### Results:

SBP/DBP control was achieved by 66% at 5 y of follow-up and 63% of pts were on ≥2 drug classes.

**Dalhof B, et al., 2002 (14)**

<table>
<thead>
<tr>
<th>Study type: RCT</th>
<th>Inclusion criteria: Men and women with ECG signs of LVH. Trough sitting SBP 160–200 mm Hg or DBP 95–115 mm Hg after 1–2 wk of placebo.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Size: 9,193 pts 55–80 y in the Losartan Intervention For Endpoint reduction in HTN</td>
<td></td>
</tr>
</tbody>
</table>

**1° endpoint:** Following a titration schedule to reach a target SBP/DBP<140/90 mm Hg

**Results:** Mean SBP/DBP at baseline was 174/98 mm Hg. Over 90% of pts required ≥2 drug classes during follow-up.

- Pts with a mean SBP/DBP of 160–200/95–115 mm Hg will need ≥2 classes of antihypertensive medication to achieve SBP/DBP <140/90 mm Hg.

**Wald DS, et al., 2009 (15)**

<table>
<thead>
<tr>
<th>Study type: Meta-analysis of RCT</th>
<th>Inclusion criteria: Randomized placebo-controlled trials comparing 2 of 4 (thiazides, BB s, ACEIs, and CCB) drug classes.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Size: 10,968 pts in 42 trials of factorial designs comparing monotherapy, combination therapy and placebo.</td>
<td></td>
</tr>
</tbody>
</table>

**1° endpoint:** Mean BP reduction.

**Results:** Combination therapy vs. monotherapy produced larger SBP reductions:
- Thiazide alone (7.3 mm Hg)
- Thiazide+second drug class (14.6 mm Hg)
- BB alone (9.3 mm Hg)
- BB +second drug class (18.9 mm Hg)
- ACE-inhibitor alone (6.8 mm Hg)
- ACE-inhibitor+second drug class (13.9 mm Hg)
- CCB alone (8.4 mm Hg)
- CCB +second drug class (14.3 mm Hg)

- Combination therapy results in substantially larger SBP and DBP reductions compared with monotherapy, even after dose titration.

**Lewington S, et al., 2002 (16)**

| Aim: To describe the age-specific relevance of BP to cause-specific mortality |
|---|---|
| Study type: Meta-analysis of cohort studies |
| Size: 61 prospective studies with 12.7 million person-y of observation, 56,000 vascular deaths in 40–89 y. |

**1° endpoint:** Not completely clear, but for our purposes, stroke and IHD death would be co-1°. Also looked at other vascular deaths.
- HRs for stroke mortality for a 20 mm Hg lower SBP by age-group
  - 40–49: 0.36 (95% CI: 0.32–0.40)
  - 50–59: 0.38 (95% CI: 0.35–0.40)
  - 60–69: 0.43 (95% CI: 0.41–0.45)
  - 70–79: 0.50 (95% CI: 0.48–0.52)
  - 80–89: 0.67 (95% CI: 0.63–0.71)
- HRs for IHD mortality for a 20 mm Hg lower SBP by age-group
  - 40–49: 0.49 (95% CI: 0.45–0.53)
  - 50–59: 0.50 (95% CI: 0.49–0.52)
  - 60–69: 0.54 (95% CI: 0.53–0.55)
  - 70–79: 0.60 (95% CI: 0.58–0.61)

- Throughout middle and old age, usual BP is strongly and directly related to vascular (and overall) mortality, without any evidence of a threshold down to at least 115/75 mm Hg.

</tr>
</tbody>
</table>

Other endpoints:
- CHD RR: 0.83 (95% CI: 0.78–0.88)
- Stroke RR: 0.73 (95% CI: 0.68–0.77)
- HF RR: 0.72 (95% CI: 0.67–0.78)
- Total deaths RR: 0.87 (95% CI: 0.84–0.91)

Other results:
- Benefit for CVD and other endpoints not different by baseline SBP, including <130 mm Hg
  - CVD: 0.63; 95% CI: 0.50–0.80; p=0.22
  - CHD: 0.55; 95% CI: 0.42–0.72; p=0.93
  - Stroke: 0.65; 95% CI: 0.27–1.57; p=0.38
  - HF: 0.83; 95% CI: 0.41–1.70; p=0.27
- More precision around estimates of benefits in SBP 130–139 at baseline, fig 4 in paper
- Results similar in trials of people with and without CVD at baseline figure 5
- CVD+ 0.77 (95% CI: 0.71–0.81)

Limitations:
- BP-lowering significantly reduces vascular risk across various baseline BP levels and comorbidities. Our results provide strong support for lowering BP to SBP<130 mm Hg and providing BP-lowering treatment to individuals with a history of CVD, CHD, stroke, DM, HF, and CKD.
- In stratified analyses, we saw no strong evidence that proportional effects were diminished in trials that included people with lower baseline SBP (<130 mm Hg), and major CV events were clearly reduced in high-risk pts with various baseline comorbidities. Both of these major findings—the efficacy of BP-lowering below 130 mm Hg and the similar proportional effects in high risk populations—are consistent with and extend the findings of the SPRINT trial.
| Law MR, et al., 2009 (18) 1945737 | Study type: Meta-analysis of use of BP-lowering drugs in prevention of CVD from 147 randomized trials | Inclusion criteria: The database search used Medline (1966 to Dec. 2007) to identify randomized trials of BP-lowering drugs in which CAD events or strokes were recorded. The search also included the Cochrane Collaboration and Web of Science databases and the citations in trials and previous meta-analyses and review articles. Exclusion criteria: Trials were excluded if there were <5 CAD events and strokes or if treatment duration was <6 mo. | 1° endpoint: CAD events; stroke Results: In 37 trials of pts with a history of CAD, BB reduced CAD events 29% (95% CI: 22%–34%). In 27 trials in which BBs were used after acute MI, BB reduced CAD events 31% (95% CI: 24%–38%), and in 11 trials in which BB were used after long-term CAD, BB insignificantly reduced CAD events 13%. In 7 trials, BB reduced stroke 17% (95% CI: 1%–30%). CAD events were reduced 14% (95% CI: 2%–25%) in 11 trials of thiazide diuretics, 17% (95% CI: 11%–22%) in 21 trials of ACEIs, insignificantly 14% in 4 trials of angiotensin receptor blockers, and 15% (95% CI: 8%–22%) in 22 trials of CCB. Stroke was reduced 38% (95% CI: 28%–47%) in 10 trials of thiazide diuretics, 22% (95% CI: 8%–34%) in 13 trials of ACEI, and 34% (95% CI: 25%–42%) in 9 trials of CCB. | • With the exception of the extra protective effect of BB given shortly after a MI and the minor additional effect of CCBs in preventing stroke, all the classes of BP-lowering drugs have a similar effect in reducing CAD events and stroke for a given reduction in BP. |
| Sundstrom J, et al., 2015 (19) 25531552 | Aim: To investigate whether pharmacologic BP reduction prevents CV events and deaths in pts with grade 1 HTN. Inclusion criteria: RCTs of at least 1 y duration; pts ≥18 y, at least 80% of whom had grade 1 HTN and no previous CVD (MI, angina pectoris, CABG, PCI, stroke, TIA, carotid surgery, peripheral arterial | 1° endpoint: Total major CV events, comprising stroke (nonfatal stroke or death from cerebrovascular disease), coronary events (nonfatal MI or death from CHD, including sudden death), HF (causing death or resulting in | Lack of individual pt data, which would have allowed a more reliable assessment of treatment effects in different pt groups. Interpretation: Lowering of BP into what has been regarded the normotensive range should therefore be routinely considered for the prevention of CVD among those deemed to be of sufficient absolute risk. |
Thomopoulos C, et al., 2014 (20) 25259547

<table>
<thead>
<tr>
<th>Aim: Investigating whether all grades of HTN benefit from BP-lowering treatment and which are the target BP levels to maximize outcome reduction.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Study type:</strong> Meta-analysis of RCTs</td>
</tr>
<tr>
<td><strong>Size:</strong> 32 RCTs with 104,359 pts</td>
</tr>
</tbody>
</table>

**Inclusion criteria:** Intentional BP-lowering comparing active drug treatment with placebo, or less active treatment (intentional BP-lowering trials), or comparison of an active drug with placebo over baseline antihypertensive treatment, resulting in a BP difference of at least 2 mm Hg in either SBP or DBP (nonintentional BP-lowering trials); enrolling of hypertensive individuals only or a high proportion (at least 40%) of them.

**Exclusion criteria:** N/A

**1° endpoint:**
- As some trials were done on low-risk pts, others on higher risk pts, no evaluation of absolute risk-reduction was made. However, a 2° analysis was done including trials or trial subgroups with mean baseline SBP/DBP values in grade 1 range and a low-to-moderate risk (<5% CV deaths in 10 y in controls): FEVER stratum with baseline SBP below the median (<153 mm Hg); HTN Detection and Follow-up Program stratum with baseline DBP 90–94 mm Hg and no CVD; OSLO (e17); TOMHS (e28) and USPHS. Risks of stroke, CHD, the composite of stroke and CHD, and all-cause death were significantly reduced by BP-lowering in these low-to-moderate risk pts (control group: average CV mortality 4.5% in 10 y) with a moderate BP elevation (average SBP/DBP 145.5/91 mm Hg) at randomization. Standardized RR associated with 10/5 reduction in BP: stroke 0.33 (95% CI: 0.11–0.98); CHD 0.68 (95% CI: 0.48–0.95)

| Study type: Meta-analysis of RCTs |
| Size: 10 RTCs with 15,266 pts |

**Inclusion criteria:** surgery, intermittent claudication, or renal failure; and compared an antihypertensive drug provided as monotherapy or a stepped-care algorithm vs. placebo or another control regimen.

**Exclusion criteria:** Excluded trials did not contribute an event for any of the outcomes of interest.

**Other endpoints:**
- Each of the above outcomes independently; and total deaths.
  - CHD 0.91 (95% CI: 0.74–1.12)
  - Stroke 0.72 (95% CI: 0.55–0.99)
  - HF 0.80 (95% CI: 0.57–1.12)
  - CVD deaths 0.75 (95% CI: 0.57–0.98)
  - Total deaths 0.78 (95% CI: 0.67–0.92)

Only the first event for a pt was used for the analysis of each outcome, but a pt who had >1 outcome type could contribute to more than 1 analysis. They also tabulated overall withdrawals and withdrawals due to adverse events.

| Meta-analyses favor BP-lowering treatment even in grade 1 HTN at low-to-moderate risk, and lowering SBP/DBP to <140/90 mm Hg. |
| Achieving <130/80 mm Hg appears safe, but only adds further reduction in stroke. |
| 5 y risks in BPLTTC control groups: CVD events 7.4%, CVD deaths 3.1% |

1° endpoint:
- CVD, other major CV events, defined as a MI, stroke, HF, or CV death, separately and combined; nonvascular and all-cause mortality; ESKD, and adverse events. Progression of albuminuria (defined as new onset of microalbuminuria/macro-albuminuria or a change from micro-albuminuria to macro-albuminuria) and retinopathy (retinopathy progression of 2 or more steps) were also recorded for trials that were done in pts with DM
- CVD RR: 0.86 (95% CI: 0.78–0.96)
- **Other endpoints:**
  - MI RR: 0.87 (95% CI: 0.76–1.00) p=0.042
  - Stroke RR: 0.78 (95% CI: 0.68–0.90)
  - HF RR: 0.85 (95% CI: 0.66–1.11)
  - CVD death RR: 0.91 (95% CI: 0.74–1.11)
  - Total deaths RR: 0.91 (95% CI: 0.81–1.03)

- Intensive BP-lowering, including to <130 mm Hg, provided greater vascular protection than standard regimens.
- In high-risk pts, there are additional benefits from more intensive BP-lowering, including for those with SBP <140 mm Hg at baseline.
- The net absolute benefits of intensive BP-lowering in high-risk individuals are large.

Limitations:
- Lack of individual pt data, which would have allowed a more reliable assessment of...

---

© 2017 American College of Cardiology Foundation and American Heart Association, Inc.
regimen group were 140/81 mm Hg, compared with 133/76 mm Hg in the more intensive treatment group.

**Other results:**
- Benefit for CVD not different by baseline SBP 120–139: 0.89 (95% CI: 0.76–1.05)
  140–160: 0.83 (95% CI: 0.68–1.00)
  >160: 0.89 (95% CI: 0.73–1.09)  
  p-heterogeneity: 0.60
- Benefit for CVD not different for more intensive and less intensive targets in intensive group  
  <140 or <150 mm Hg: 0.76 (95% CI: 0.60–0.97)
  <120–<130 mm Hg: 0.91 (95% CI: 0.84–1.00; p-hetero: 0.06)
- Absolute benefits were proportional to absolute risk.
  - For trials in which all pts had vascular disease, renal disease, or DM at baseline, the average control group rate of major vascular events was 2.9% per y compared with 0.9% per y in other trials, and the numbers needed to treat were 94 (95% CI: 44–782) in these trials vs. 186 (95% CI: 107–708) in all other trials.
  - Increase in Severe hypotension: 0.3% vs. 0.1% per person y OR: 2.68 (95% CI: 1.21–5.89)

**Interpretation:** Supports treating pt with and without CVD at threshold of 130 to 120, supports treating at threshold of about 130 even down to a CVD event rate of 0.9% per y.

---

**Study type:**
- **U.S. Preventive Services Task Force commissioned systematic review and meta-analysis of office and out of office BP relationships for diagnostic accuracy of diagnosing high BP after an initial office-based classification of high BP.**

**Inclusion criteria:**
- Adults ≥18 y.
- 24 studies based on “confirmation” by means of ABPM and 6 by means of HBPM.
- CVD risk-relationships for ABPM, HBPM and office-based BPs also reviewed.
- ABPM was recommended as the best method to confirm an office-based diagnosis of high BP, with HBPM an acceptable alternative, based on “over diagnosis” of high BP with office BP measurements (White coat hypertension) and stronger relationships between out of office BP measurements (especially ABPM) with vascular events.

**1° endpoint:**
- ABPM or HBPM conformation of office-based diagnosis of high BP.

**Notes:**
- Adult ≥18 y.
- 24 studies based on “confirmation” by means of ABPM and 6 by means of HBPM.
- CVD risk-relationships for ABPM, HBPM and office-based BPs also reviewed.
- ABPM was recommended as the best method to confirm an office-based diagnosis of high BP, with HBPM an acceptable alternative, based on “over diagnosis” of high BP with office BP measurements (White coat hypertension) and stronger relationships between out of office BP measurements (especially ABPM) with vascular events.

**Screen for high BP in adults ≥18 y and confirm office-based high BP using out of office BP measurements (preferably ABPM).**

Similar prevalence using either 24-h or awake ABPM

Overlap from daytime to 24-h ABPM: WCH=86% MH=61%

No difference in proportions of pts Dx with MH or WCH by HBPM or awake ABPM

No difference between treated and untreated. However, only 44% overlap for MH, but 90%–95% if 5 mm Hg zone of uncertainty added.

<td>Muxfeldt ES, et al., 2015 (60) 25601933</td>
<td><strong>Aim:</strong> Evaluate the effect of CPAP on pts with resistant hypertension and OSA.  <strong>Study type:</strong> RCT  <strong>Size:</strong> 434 pts; 6 mo of follow-up</td>
<td><strong>Inclusion criteria:</strong> Pts with resistant hypertension and OSA</td>
<td><strong>Intervention:</strong> CPAP + conventional antihypertensive therapy  <strong>Comparator:</strong> Antihypertensive therapy alone. Conventional antihypertensive therapy included spironolactone.</td>
<td><strong>1° endpoint:</strong> BP reduction at 6 mo via ABPM  <strong>Results:</strong>  • On an intention-to-treat analysis, there was no significant difference in any BP change, neither in nocturnal BP fall, between CPAP and control groups. The best effect of CPAP was on night-time SBP in per-protocol analysis, with greater reduction of 4.7 mm Hg (95% CI: -1.6%–5.8%; p=0.25, in comparison with the control group.  • Median use of CPAP was 4.8 h.</td>
<td><strong>Limitations:</strong> Nonblinded design; per-protocol analysis underpowered to show the prespecified outcome of 6–7 mm Hg SBP differences between CPAP and control groups.  <strong>Conclusions:</strong> CPAP had no significant effect on clinic or ambulatory BP in pts with resistant hypertension and moderately severe to severe OSA. However, in the specific subgroup of pts with uncontrolled ambulatory BP, CPAP may modestly reduce night-time SBP and improve the nocturnal BP fall pattern. The reason for lack of BP reduction in the overall study may have been due to excellent control of BP with median 5 medications, including spironolactone, in the majority of pts.</td>

Aim: Study the effect of fiber supplementation on BP

Study type: Systematic review and meta-analysis

Size: 28 trials met the inclusion criteria and reported fiber intake and SBP and/or DBP. 18 trials were included in a meta-analysis.

Inclusion criteria:
- RCTs, in humans of at least 6 wk duration
- Fiber isolate or fiber-rich diet against a control or placebo
- Published between 1 January 1990 and 1 December 2013.

Exclusion criteria: N/A

Intervention: Fiber supplementation (average dose =11.5 g/d) -soluble fiber in 11 trials, insoluble fiber in 7 trials, and a mixture in the remaining trials

Comparator: Placebo or no fiber supplementation

1° endpoint: Studies were categorized into 1 of 12 fiber-type categories. The pooled estimates for all fiber types were -0.9 mm Hg (95% CI: -2.5–0.6 mm Hg) and -0.7 mm Hg (95% CI: -1.9–0.5 mm Hg) for SBP and DBP, respectively. The median difference in total fiber was 6 g. Analyses of specific fiber types concluded that diets rich in beta-glucans reduce SBP by 2.9 mm Hg (95% CI: 0.9, 4.9 mm Hg) and DBP by 1.5 mm Hg (95% CI: 0.2–2.7 mm Hg) for a median difference in beta-glucans of 4 g. Heterogeneity for individual fiber types was generally low.

Safety endpoint: N/A

Higher consumption of beta-glucan fiber is associated with lower SBP and DBP.

The results of this review are consistent with recommendations to increase consumption of foods rich in dietary fiber, but some additional emphasis on sources of beta-glucans, such as oats and barley, may be warranted.

---

|                                      |                                          | - Previous meta-analyses have been conducted by Appel et al (1993), Morris et al. (1993), Geleijnse et al (2002) and Dickinson et al. (2006). |
|                                      |                                          | - In general, the findings have been fairly consistent in demonstrating a relatively small (2 3/4 mm Hg SBP) but significant effect, with most of this being attributable to the results in trials conducted in hypertensive pts. |
**Rodriguez-Leyva D, et al., 2013 (66) 24126178**

**Aim:** Study the effect of flaxseed on BP in hypertensive pts  
**Study type:** RCT  
**Size:** 110 pts with PAD

**Inclusion criteria:**  
- >40 y  
- PAD for >6 mo, ABI <0.9  

**Exclusion criteria:**  
- Inability to walk, bowel disease, moderate to severe renal failure, life expectancy <2 y with high cardiac risk, allergy to any of the study products, pts who plan to undergo surgery during the course of the trial, and no more than 2 fish meals per wk

**Intervention:** Pts given 1 food item per day for 6 mo, containing either 30 g of milled flax seed or placebo. Flaxseed contains omega-3 fatty acids, lignans, and fiber.  
**Comparator:** Placebo

**1° endpoint:** SBP and DBP consistently decreased in the flaxseed group over the course of the study. After 6 mo, SBP in the flaxseed group dropped significantly to 136±22 mm Hg (p=0.04). On the contrary, in the placebo group, SBP rose slightly to 146±21 mm Hg. After 6 mo of intervention, DBP in the flaxseed group fell to 72±11 mm Hg (p=0.004), whereas DBP in the placebo group remained the same (79±10 mm Hg).

- Based on this 1 RCT, flaxseed appeared to have a significant BP lowering effect

| Whelton PK, et al., 1997 (67) 9168293 | Aim: Study the effect of potassium supplementation on BP  
**Study type:** Systematic review and meta-analysis  
**Size:** | Inclusion criteria:  
- Human RCT  
- Without HTN  
- Potassium supplementation vs. control  
- No concurrent interventions  
**Exclusion criteria:** Missing key data  
**Intervention:** Potassium supplementation in 1,049 pts (potassium chloride tabs in 10 RCTs with 618 pts and diet in 2 RCT with 431 pts)  
**Comparator:** No potassium supplementation | 1° endpoint:  
- Significant reduction in BP.  
- Overall (hypertensives and normotensives), mean: 3.11 mm Hg; 95% CI: -4.32– -1.91 mm Hg.  
- In the 12 trials conducted in normotensives, mean: -1.8 mm Hg; 95% CI: -2.9– -0.6 mm Hg for SBP and -1.0 mm Hg; 95% CI: -2.1–0.0 for DBP  
- This is the most comprehensive presentation of the effects of potassium on BP, including experience in normotensives.  
- Significant reduction in SBP overall and in the subgroups with and without HTN.  
- In a subsequent meta-analysis of 23 trials, Geleijnse JM, Kok FJ, and Grobbee DE (J Hum Hypertens. 2003;17:471-480) reported a similar effect of potassium on SBP in both hypertensives and nonhypertensives (mean of -3.2 and -1.4 mm Hg, respectively). |

</tbody>
</table>
pts. 12 of the RCTs (14 comparisons) were conducted in 2,240 normotensive pts.

Safety endpoint:
In the small number of relevant trials (which included both hypertensive and normotensive pts) that provided safety endpoint measurements (4–14 trials), there was no change in total, LDL- or HDL-cholesterol, or triglyceride levels. There were small significant increases in plasma renin activity, aldosterone, and noradrenaline levels but these were consistent with expected physiologic responses to sodium reduction.

Graudal NA, et al., 2012 ([76](#))

**Aim:** Study the effect of sodium reduction on BP

**Study type:** Systematic review and meta-analysis

**Size:** Overall study included 167 trials. Of these, 71 RCTs were conducted in 5,577 normotensive pts, with the following characteristics:
- Median age: 27 y (13–67 y)
- Median trial duration: 7 d (4–1,100 d)
- 5,292 Whites (71 studies)
- 268 Blacks (7 studies)
- 215 Asians (3 studies)

**Inclusion criteria:**
- RCTs
- 24-h collections or estimates from ≥8 h collections of urinary sodium excretion

**Exclusion criteria:**
Systematic studies in unhealthy pts with diseases other than HTN

**Intervention:** Sodium reduction

**Comparator:** No sodium reduction

**1° endpoint:** The overall effect of sodium reduction was not presented.

A forest plot of 71 comparisons (from 61 trials) in the 4,919 normotensive whites assigned to sodium reduction compared to usual sodium intake identified a trend towards lower SBP in 50 (70%), no difference in 8 (11%), and higher SBP in 13 (19%). In a pooled analysis, sodium reduction compared to usual sodium intake in the normotensives yielded the following MDs in SBP:
- Whites: -1.27 (95% CI: -1.88– -0.66)
- Blacks: -4.02 (95% CI: -7.37– -0.68)
- Asians: -1.27 (95% CI: -3.07– -0.54)

A corresponding analysis in the hypertensives yielded the normotensives yielded the following MDs in SBP:
- Whites: -5.48 (95% CI: -6.53– -4.43)
- Blacks: -6.44 (95% CI: -8.85– -4.03)
- Asians: -10.21 (95% CI: -16.98– -3.44)

**Safety endpoint:** In the relevant trials (all cross-over studies and including

- Heterogeneous group of trials that included many small studies of short duration in young persons.
- Overall finding of lower BP in those assigned to a reduced intake of dietary sodium, with an apparently greater effect in Blacks compared to Whites and Asians.
- The hormone changes in this meta-analysis likely reflect a physiologic response to sodium reduction, especially in studies of short duration and rapid changes in sodium intake. The increases in total cholesterol and triglyceride levels were not noted in the meta-analyses conducted by Aburto et al. and He et al.
comparisons in both hypertensive and normotensive participants) that provided safety endpoint measurements, significant increases in the standard MD for plasma renin activity (70 trials), aldosterone (51 trials), noradrenaline (31 trials), adrenaline (14 trials), and weighted MD for total cholesterol (24 trials), and triglyceride (18 trials) levels. There was no significant effect of sodium reduction on LDL-cholesterol (15 trials) and HDL-cholesterol (17 trials).

### DASH-Sodium Trial

**Aim:** Study the effect of sodium reduction on BP  
**Study type:** Randomized, controlled crossover trial  
**Size:** Overall study based on 412 pts, of whom 243 were normotensive

**Inclusion criteria:**  
- Adults ≥22 y  
- Taking antihypertensive medication, heart disease, renal disease, poorly controlled hyperlipidemia or DM, DM requiring insulin, special dietary requirements, >14 drinks/wk

**Exclusion criteria:**  
- Taking antihypertensive medication, heart disease, renal disease, poorly controlled hyperlipidemia or DM, DM requiring insulin, special dietary requirements, >14 drinks/wk

**Intervention:** Feeding study in which pts were randomized to a DASH or control diet at 3 levels of assigned dietary sodium intake  
- High=210 mmol/d  
- Intermediate=100 mmol/d  
- Low=50 mmol/d

**Comparator:** Each pt served as their own control (crossover design)

**1° endpoint:**  
- Reduced sodium intake resulted in a significant reduction in SBP, with a greater reduction during assignment to the Low compared to the Intermediate sodium intake diet. At every level of sodium intake, the achieved reduction in SBP was greater on the control group compared to the DASH diet and for Blacks compared to other pts.  
- Reducing sodium intake from the high to intermediate level decreased SBP by 2.1 mm Hg (p<0.001) during the control diet and 1.3 mm Hg (p=0.03) during the DASH diet.  
- Reducing sodium intake from the intermediate to low level decreased SBP by a further 4.6 mm Hg (p<0.001) during the control diet and 1.7 mm Hg (p<0.01) during the DASH diet.

**Safety endpoint:** N/A

### TOHP II Trial (Sodium component)

**Aim:** Study the effect of sodium reduction on BP and prevention of HTN.  
**Study type:** Randomized,  
**Inclusion criteria:**  
- Healthy community-dwelling adults 30–54 y  
- BMI between 110% and 165% of desirable body weight

**Intervention:** Behavior change intervention aimed at studying the effects of modest (25%–30%) reductions in dietary sodium intake during

**1° endpoint:**  
- Compared to usual care, the sodium reduction group experienced a significant mean reduction of 51 mmol for 24-h urinary excretion and -2.9 (SD: 0.5) mm Hg (p<0.001) in SBP at 6 mo (-5.1 mm Hg in

**Safety endpoint:** N/A

- This trial provides the best (direct) evidence for a dose-response treatment relationship between sodium intake and level of BP.
- It also suggests the relative effect of reduced sodium intake is greater in persons with a typical U.S. diet but the combination of sodium reduction and consumption of a DASH-type diet results in a lower level of BP than can be achieved with either dietary modification on its own.
- Consistent with other trials and meta-analyses, it suggests the effect of a reduced sodium intake is greater in Blacks compared to others, especially for those consuming a typical U.S. diet.
### TOHP Phase I

**Aim:** Study the effect of sodium reduction on BP and prevention of HTN  
**Study type:** Randomized, controlled factorial trial.  
**Size:** Overall, 2,182 adults, with the 327 assigned to sodium reduction compared

**TOHP Phase I**  
1992 (79)  
1586398

- Not taking BP-lowering medication  
- Mean SBP <140 mm Hg and DBP 83–89 mm Hg  

**Exclusion criteria:**  
- Taking antihypertensive medication  
- Heart disease, renal disease, poorly controlled hyperlipidemia or DM, DM requiring insulin, special dietary requirements, >14 drinks/wk.

- Mean SBP <140 mm Hg and DBP 83–89 mm Hg

**Comparator:** Usual care group

- Up to 48 mo (minimum 36 mo) of follow-up.

- The sodium reduction group and -2.2 mm Hg in the usual care group.

- A progressive reduction in effect size for urinary sodium excretion and BP was noted over time, with mean for SBP at 18, 36 mo and termination of -2.0 (SD: 0.5) mm Hg (p<0.001), -1.2 (SD: 0.5) mm Hg (p=0.02), and -1.0 (SD: 0.5) mm Hg (p=0.5).

**Prevention of HTN**  
- At 6 mo of follow-up the incidence of new onset HTN was 39% lower in the pts randomized to reduced dietary sodium intake compared to the usual care group (p=0.04).  
- During more prolonged follow-up, the effect size decreased but remained significant after 48 mo of follow-up (14% reduction; p=0.04). Overall, the incidence of HTN was reduced by 18% (p=0.048).

**Safety endpoint:** N/A

- Significantly lower DBP (0.9 mm Hg; p<0.05) and SBP (1.7 mm Hg; p<0.01) in the sodium reduction group compared to usual care  
- Few CVD events  
- No difference in symptoms  
- Significant improvement in general well-being at 6 and 18 mo (p<0.05)

| Appel LJ, et al., 1997 (82) 9099655  | Aim: Study the effect of dietary patterns on BP  
Study type:  
• Multicenter RCT  
• 3 arm parallel design  
• 3 wk pre-randomization run-in phase  
• Feeding study with 8 wk of intervention  
Size: 459 adults, mean age 44 y. (326 normotensive) | Inclusion criteria:  
• Adults ≥22 y  
• SBP=160 mm Hg and DBP 80–95 mm Hg  
• No antihypertensive medication  
Exclusion criteria:  
• CVD event within 6 mo  
• Poorly controlled DM or hyperlipidemia  
• BMI ≥35  
• Pregnancy or lactation  
• Chronic illness that would interfere with participation  
• Unwillingness to stop taking vitamins, mineral supplements, Ca++ antacids | Intervention:  
• Diet high in fruits and vegetables  
• “Combination” diet high in fruits, vegetables, low-fat dairy products, and reduced total fat, saturated fat and cholesterol.  
Comparator: Usual U.S. diet | 1° endpoint: Compared to the control diet, both intervention diets reduced BP, with an overall mean (95% CI) reduction of:  
• Fruits and Veg. Diet: SBP: -2.8 (95% CI: -4.7– -0.9)  
DBP: -1.1 (95% CI: -2.4– -0.3)  
• Combination Diet: SBP: -5.5 (95% CI: -7.4– -3.7)  
DBP: -3.0 (95% CI: -4.3– -1.6)  
The BP changes in the subgroup with HTN were:  
• Fruits and Veg. Diet: SBP: -7.2 (-11.4, -3.0)  
DBP: -2.8 (-5.4, -0.3)  
• Combination Diet: SBP: -11.4 (-15.9, -6.9)  
DBP: -5.5 (-8.2, -2.7) | • This trial was the first of several to document the value of the combination diet (later renamed the DASH diet).  
• The BP reductions noted with the DASH (combination) diet were substantial and well maintained.  
• Generalizability was limited due to the nature of the intervention (feeding study) and the relatively short period of intervention experience (8 wk)
### Study Details

**Aim:** Study the effect of different levels of sodium intake on BP during consumption of a DASH or usual U.S. diet.

**Study type:**
- Multicenter RCT with 2 parallel diet arms (DASH diet or usual U.S. diet)
- Within each arm, randomized cross-over trial with 3 periods testing different levels of sodium intake (no washout)

**Size:** 412, with 59% (243) being normotensive

**Inclusion criteria:**
- Adults ≥22 y
- Average SBP between 120–159 mm Hg and average DBP between 80–95 mm Hg
- No use of antihypertensive medication

**Exclusion criteria:**
- Heart disease, renal insufficiency, poorly controlled hyperlipidemia or DM, DM requiring insulin, special dietary requirements, >14 alcoholic drinks /wk.

**Intervention:** 3 levels of dietary sodium while consuming a DASH or usual U.S. diet. The target sodium intake levels for a daily energy intake of 2,100 kcal were:
- High: 150 mmol (3,450 mg)/d
- Intermediate: 100 mmol (2,300 mg)/d
- Low: 50 mmol (1,150 mg)/d

The mean achieved levels of sodium during the high, intermediate and low sodium periods were 144, 107 and 67 mmol/d in the DASH diet group and 141, 106, and 64 mmol/d in the usual U.S. diet group.

**Comparator:** See description above

**1st endpoint:**
- At each level of sodium intake, SBP and DBP were lower during consumption of the DASH diet compared to the usual U.S. diet, the difference being greatest with high sodium intake and lowest with low sodium intake, with the mean SBP difference between the DASH and usual US diets during high, intermediate and low sodium intake being -5.9 (95% CI: -8.0– -3.7), -5.0 (95% CI: -7.6– -2.5), and -2.2 (95% CI: -4.4– -0.1). The corresponding differences for DBP were -2.9 (95% CI: -4.3– -1.5), -2.5 (95% CI: -4.1– -0.8), and -1.0 (95% CI: -2.5, 0.4).
- In both the DASH and usual U.S. diet arms, SBP and DBP were significantly lower during intermediate compared to high sodium intake, and during low compared to intermediate sodium intake, with the decrement being greater for the latter change.
- In comparison to consumption of a usual U.S. diet at the high level of sodium intake.

**1° Safety endpoint:** Infrequent and similar occurrence of gastrointestinal symptoms in each group.
**Aim:** Study the effect of 2 behavioral interventions, aimed at dietary change, on BP

**Study type:**
- Multicenter RCT with 3 parallel arms:
  - Established
  - Established plus DASH diet
  - Advice only

**Size:**
- 810 adults, with 62% (506) normotensive. At baseline, mean age, BMI and SBP/DBP were 50 y, 33 kg/m², and 135/85 mm Hg, respectively.

**Duration:** 6 mo, with observations at 3 and 6 mo.

**Inclusion criteria:**
- Adults ≥25y
- Average SBP between 120–159 mm Hg and average DBP between 80–95 mm Hg
- No use of antihypertensive medication
- BMI between 18.5 and 45 kg/m²
- Regular use of drugs that affect BP
- Target organ damage or DM
- Use of weight-loss meds
- Hx CVD event
- HF, angina, cancer, within 2 y
- Consumption of >21 alcoholic drinks /wk
- Pregnancy, planned pregnancy, lactation

**Intervention:**
- Structured behavioral interventions that used an identical format (4 individual and 14 group sessions) to facilitate adoption of “established” dietary recommendations for reduction in BP or “established” plus the DASH diet. The “established” dietary recommendations used in PREMIER were a) weight loss in overweight participants, b) sodium reduction, increased physical activity, reduced alcohol intake in pts consuming alcohol.

**Exclusion criteria:**
- No use of antihypertensive medication
- BMI between 18.5 and 45 kg/m²
- Regular use of drugs that affect BP
- Target organ damage or DM
- Use of weight-loss meds
- Hx CVD event
- HF, angina, cancer, within 2 y
- Consumption of >21 alcoholic drinks /wk
- Pregnancy, planned pregnancy, lactation

**1° endpoint**
- Compared to control (advice only), SBP and DBP were significantly reduced with both active interventions but there was no significant difference in the effect size between the 2 active intervention groups. This was true for both the normotensive and hypertensive pts, with the effect size being larger in the hypertensive group. In the normotensives, the MD for change in SBP was identical for the “established” compared to “established plus DASH Diet” groups: -3.1 (95% CI: -5.1--1.1) mm Hg
- The corresponding changes for DBP were -1.6 (95% CI: -2.9--0.2) for the “established” intervention group and -2.0 (95% CI: -3.4--0.6) for the “established intervention plus DASH Diet” group.

**Overall, the incidence of HTN was lowest and the percent with optimal BP was highest in the “established plus DASH” diet but the incidence of sodium intake, the normotensive group consuming the DASH diet at the low level of sodium intake had a mean SBP difference of 7.1 mm Hg (p<0.001).**

**1° Safety endpoint:** Participants tended to report less symptoms during periods of reduced sodium intake, with a statistically significant reduction in reports of headache (p<0.05) consistent with prior experience in the TONE trial.

This was an interesting trial which employed a behavior change approach to implement both active interventions.

The investigators goal was to determine the additive value of the DASH Diet in persons already following key elements of conventional (established) recommendations for nonpharmacologic intervention to lower BP.

The intervention approach in this trial was less effective in achieving weight loss and reduction in dietary sodium compared to the corresponding experience in the TOHP and TONE trials and the DASH Diet effects on intermediate variables (such as fruit and vegetable consumption) was less than that achieved in the DASH Diet feeding studies.

Despite the modest intervention effects, both SBP and DBP were significantly reduced with the conventional intervention approach (in normotensives as well as overall) and addition of the DASH diet did not have a
intervention goals in the “established” group, with a MDs of 3.8 kg (8.4 lbs) for body weight, 11.6 mmol (267 mg)/d for urinary sodium excretion, no change in physical activity (but better fitness), and no change in alcohol consumption (but very low alcohol consumption at baseline).

- Weight loss was somewhat greater in the “established” plus DASH diet group, with a MD of 4.8 kg (10.6 lbs) for body weight. This group also manifested expected effects of the DASH diet, with significantly higher urinary potassium and phosphorous levels, greater consumption of fruits and vegetables, dietary calcium, dairy products, and a lower consumption of total fat and saturated fat.

Comparator: Advice only

HTN was significantly less and the percent with optimal BP was higher in both active intervention groups compared to advice only. The difference between the 2 active intervention groups was not significant. In the normotensives, there was a nonsignificant trend towards less HTN and a significantly higher percent with optimal BP in both active intervention groups compared to advice only, with no significant difference for percent with optimal BP in the 2 active intervention groups.

1° Safety endpoint: N/A

- There were some nonsignificant trends for slightly lower BP, less HTN, and more optimal BP in the “established plus DASH Diet” group compared to “established” group. The authors also cited use of the DASH Diet as a means to beneficially influence CVD risk factors in addition to BP.

Aim: Compare effects of 3 diets, each with a reduced intake of saturated fats, on BP and serum lipids

Inclusion criteria:
- Adults ≥30 y
- Average SBP between 120–159 mm Hg and

Intervention: High protein with reduced fat/saturated fat content

1° endpoint

Compared with the high carbohydrate diet, the high protein diet:

- This clinical trial demonstrated that substituting either protein or monounsaturated fat in place of carbohydrate resulted in a small
Study type:
- 2 center RCT
- 3 period crossover design
- Each 8 wk period was separated by a 2–4 wk wash-out phase

Size: 161–164 included in analyses (191 pts randomized). 132 (80.5%) of the 164 included in the BP analyses were normotensive. Mean age and BMI were 54 y and 30.2 kg/m², respectively.

Inclusion criteria: DM, CVD (current or H/O), LDL cholesterol >220 mg/dL, fasting triglycerides >750 mg/dL, weight >350 lb., taking that effect BP or lipids, unwillingness to stop vitamin/mineral supplements, >14 alcoholic drinks/wk.

Exclusion criteria: DM, CVD (current or H/O), LDL cholesterol >220 mg/dL, fasting triglycerides >750 mg/dL, weight >350 lb., taking that effect BP or lipids, unwillingness to stop vitamin/mineral supplements, >14 alcoholic drinks/wk.

Comparator: High carbohydrate with reduced fat/saturated fat content

Intervention:
- Reduced SBP by -1.4 mm Hg (p=0.002) overall and by -0.9 mm Hg (p=0.047) in the normotensives
- Reduced LDL cholesterol by 3.3 mg/dL (p=0.01) overall and by -2.1 mg/dL (p=0.14) in the normotensives
- Reduced HDL-C by -1.3 mg/dL (p=0.02) overall
- Reduced serum Triglycerides by -15.7 mg/dL (p=0.001) overall

Compared with the high carbohydrate diet, the high unsaturated fat diet:
- Reduced SBP by -1.3 mm Hg (p=0.005) overall and by -0.9 (p=0.06) in the normotensives
- Reduced LDL cholesterol by -1.5 mg/dL (p=0.01) and by -2.1 (p=0.14) in the normotensives
- Increased HDL-C by 1.1 mg/dL (p=0.03) overall
- Reduced serum Triglycerides by -9.6 (p=0.02) overall

Aim: Compare the effects of a low-carbohydrate and a low-fat diet on body weight and CVD risk factors (including BP)

Study type: Single center parallel arm RCT that compared the 2 diets over 12 mo of intervention.

Size: 148 pts, with a mean age of 46.8 y at entry

Inclusion criteria: 22–75 y
- BMI: 30–45 kg/m²

Exclusion criteria: CVD
- DM-2
- Kidney disease
- Use of prescription weight loss meds/surgery
- Weight loss >6.8 kg during prior 6 mo

Comparator: Low fat diet, with <30% of daily energy

Intervention:
- Low-carbohydrate diet, with digestible carbohydrate (total carbohydrate minus total fiber) <40 g/d
- Behavioral counselling that employed a mix of 20 individual and group meetings

1° endpoint:
- Compared to the low-fat diet group, the low-carbohydrate diet group had a mean decrease at 12 mo of:
  - Body weight: -3.5 (95% CI: -5.6– -1.4) kg
  - Fat mass: -1.5 (95% CI: -2.6– -0.4) kg
  - HDL-C: 7.0 (11.0–3.0) mg/dL
  - Ratio total/HDL-C: -0.44 (95% CI: -0.71– -0.16)
  - Sr. triglyceride: -14.1 (95% CI: -27.4– -0.8) mg/dL

This clinical trial provides 1 of the longest follow-up experiences related to the topic.
- It suggests low carbohydrate diets may be somewhat better than traditional low fat diets in achievement of weight loss, improvement of lipid profile, inflammation, and CHD risk.
- Although the BP differences were not significant, there was a consistent trend toward lower BPs in the low-carbohydrate diet group.
baseline. Mean SBP/DBP at baseline were 124.9/79.4 and 120.3/77.5 mm Hg in the low-fat and low-carbohydrate groups, respectively. The corresponding BMIs were 97.9 and 96.3 kg/m². All 148 pts were included in the analysis (intention to treat)

<table>
<thead>

<tbody>
<tr>
<td>Behavioral counselling that used identical format to that employed in the low carbohydrate group</td>
</tr>
</tbody>
</table>

- At 3, 6, and 12 mo. BP tended to be lower in the low-carbohydrate group but none of the differences in SBP or DBP were significant.
- CRP was reduced in both diet groups but to a significantly greater extent in the low-carbohydrate group.
- At 6 and 12 mo pts in the low carbohydrate group experienced a significant improvement in their 10-y Framingham CHD risk score. In contrast, there was no change in Framingham CHD risk in the low-fat diet group.

**1° Safety endpoint**: No serious side effects noted

</table>

- This systematic review/meta-analysis tends to suggest low-carbohydrate diets are somewhat more effective in reducing body weight compared to the traditionally recommended low-fat diets.
- Although the BP differences were not significant they would probably have reached a conventional level of significance had subsequent clinical trials (including the Bazzano et al. trial) been included in the analysis.

**Aim**: Compare effects of low-carbohydrate and low-fat diets on weight loss and CVD risk factors

**Nordmann AJ, et al., 2006 (86) 16476868**
### Nordmann AJ, et al., 2011 (87) 21854893

**Aim:** Compare effects of Mediterranean and low-fat diets on weight loss and CVD risk factors  
**Study type:**  
- Systematic review and meta-analysis  
- Cochrane Collaboration strategy  
**Size:** 6 trials (2,650 pts)  
**Inclusion criteria:**  
- RCT  
- Intent to treat analysis  
- Overweight/obese with at least 1 additional CVD risk factor  
- Follow-up ≥6 mo  
**Exclusion criteria:** N/A  
**Intervention:** Mediterranean diet: moderate fat intake (main sources olive oil and nuts), rich in vegetables, and low in red meat.  
**Comparator:** Low fat diet: ≤30% of energy intake from fat

**1° endpoint:** Compared to the low-fat diet, the Mediterranean diet resulted in MDs of:  
- Body weight: -2.2 (95% CI: -3.9 – -0.6) kg  
- BMI: -0.6 (95% CI: -1.0– -0.1) kg/m²  
- SBP: -1.7 (95% CI: -3.3– -0.05) mm Hg  
- DBP: -1.5 (95% CI: -2.1-- -0.8) mm Hg  
- Fasting Plasma Glucose: -3.8 (95% CI: -7.0– -0.6) mg/dL  
- Total-Cholesterol: -7.4 (95% CI: -10.3– -4.4)  
- CRP: -1.0 (95% CI: -1.5-- -0.5)  
**1° Safety endpoint:** N/A

- Overall, this study suggests the Mediterranean diet compared to the traditional low fat diet results in greater weight loss, a better CVD risk factor profile (including better BP control), and less inflammation.  
- The number of eligible trials was small and the study samples were heterogeneous (2 2° and 4 1° prevention trials).

### Yokoyama Y, et al., 2014 (88) 24566947

**Aim:** Compare the effects of vegetarian and omnivorous diets on BP  
**Study type:** Systematic review and meta-analysis  
**Size:**  
- 7 trials (n=311).  
- 6 were RCT (n=198)  
- 4 parallel and 3 cross-over designs  
- All were open  
- Follow-up ≥6 wk (mean=15.7 wk)  
- Mean age=44.5 y  
**Inclusion criteria:**  
- Adults ≥20 y  
- English language publications between Jan 1946-Nov 2013  
**Exclusion criteria:**  
- Twin pt studies  
- Multiple interventions  
- Only categorical BP results  
**Intervention:**  
- Lacto-ovo in 4 trials  
- Lacto in 1 trial  
- Vegan in 2 trials  
**Comparator:** Omnivorous diet in all trials

**1° endpoint:** Compared to the omnivorous diet, the vegetarian diet resulted in MDs of:  
- SBP: -4.8 (95% CI: -6.6– -3.1) mm Hg  
- DBP: -2.2 (95% CI: -3.5-- -1.0) mm Hg  
- Fasting Plasma Glucose: -3.8 (95% CI: -7.0-- -0.6) mg/dL  
- Total-Cholesterol: -7.4 (95% CI: -10.3-- -4.4)  
- CRP: -1.0 (95% CI: -1.5-- -0.5)  
**1° Safety endpoint:** N/A

- Overall, this meta-analysis of clinical trials suggested BP was lower in those who consumed a vegetarian diet compared to their counterparts who consumed an omnivorous diet.  
- However, the trials were generally small, heterogeneous in their design and conduct, and of questionable quality.  
- Even greater reductions in SBP and DBP were noted in a MA of 32 observational studies.

### PREDMED

Toledo E, et al., 2013 (89) 24050803

**Aim:** Compare the effects of a Mediterranean and lower-fat diet on BP  
**Inclusion criteria:**  
- Adults, men 5,580 y, women 60–80 y  
- Free from CVD  
**Intervention:** Pts assigned to a control group or to 1 of 2 Mediterranean diets.

**1° endpoint:** The percentage of pts with controlled BP increased in all 3 intervention groups (p-value for within-group changes: p<0.001). Pts

- Overall, this study suggests the traditional Mediterranean diet and a low-fat diet exerted beneficial effects on BP and could be part of advice to pts for controlling BP.
**Study type:** RCT, single-blinded, in Spanish primary healthcare centers  
**Size:** 7,447 men (55–80 y) and women (60–80 y) at high risk for CVD.  

**Exclusion criteria:** Do not meet criteria listed above  

**Comparator:** Lower fat diet

The control group received education on following a low-fat diet, while the groups on Mediterranean diets received nutritional education and also free foods; either extra virgin olive oil, or nuts.

**Endpoint Results:**

- Lower values of DBP were noted in the 2 groups following the Mediterranean diet with extra virgin olive oil or with nuts than in the control group.

#### Data Supplement 16. RCTs and Meta-analysis RCTs Studying the Effect of Nonpharmacologic Interventions on BP (Alcohol Reduction) (Section 6.2)

| Xin X, et al., 2001 (90) 11711507    | **Aim:** Study the effect of alcohol reduction on BP  
**Study type:** Systematic review and meta-analysis  
**Size:** 15 RCTs (25 comparisons) with 2,234 pts.  
6 trials were conducted in normotensives (269 pts with a mean age ranging from 26.5–45.5 y). Average  
| **Inclusion criteria:**  
- RCT in humans  
- Publication between 1966-1999  
- Duration ≥1 wk  
- Only pts regularly consuming alcohol  
- Only difference between the comparison groups was alcohol intake  
**Exclusion criteria:** Comparison of different doses of alcohol intake  
**Intervention:** Reduction in alcohol consumption. In most trials this was achieved by randomization to “light” alcohol but some RCT were based on a behavioral intervention aimed at reducing the number of drinks consumed.  
**Comparator:** Usual consumption of alcohol  
| **1° endpoint:**  
- Overall, alcohol reduction was associated with a significant reduction in mean SBP of -3.31 (95% CI: -4.10– -2.52) and DBP of -2.04 (95% CI: -2.58– -1.49).  
- In the subgroup of 7 RCTs in persons with HTN, the mean changes in SBP and DBP were -3.9 (95% CI: -5.04– -2.76) and -2.41 (95% CI: -3.25– -1.57).  
- In the subgroup of 6 RCTs in normotensives the corresponding changes in SBP and DBP were -3.5 (95% CI: -4.51– -2.51) and -1.80 (95% CI: -3.03– -0.58).  
| **This is the most recent meta-analysis of this topic. Although this meta-analysis reports % reduction in alcohol intake, most trials aimed at reducing the number of alcoholic drinks consumed achieved a reduction of about 3 drinks/d.  
**The intervention results were consistent with the relationship alcohol and BP in observational epidemiology – about a 1 mm Hg higher SBP per alcoholic drink consumed. In observational studies, type of alcohol does not seem to matter and at lower levels of alcohol consumption (<1 standard size alcoholic drink per day in women and <2 in men) there does not...

</table>
| **Design:**  
  • 15 parallel-arm trials  
  • 21 crossover trials |
| **Setting:**  
  • 13 in hypertension  
  • 13 in normotension  
  • 12 HTN and NT  
  • Only 3 trials presented data for women. |
| **Inclusion criteria:**  
  • RCT in adult humans  
  • Publication on or before July 13, 2016.  
  • Full text articles.  
  • Change in alcohol intake for ≥1 wk |
| **Intervention:** Reduction in alcohol consumption. Strategy varied from controlled inpatient administration to randomization to "light" alcohol to pragmatic primary care trials with counselling to reduce alcohol intake. |
| **Duration:** Follow-up from 1 wk to 2 y (median 4 wk). |
| **Safety endpoint:** N/A |

**1° endpoint:**  
- Overall, alcohol reduction was associated with a significant reduction in mean SBP of -3.31 (95% CI: -4.10– -2.52) and DBP of -2.04 (95% CI: -2.58– -1.49).  
- In the subgroup of 7 RCTs in persons with HTN, the mean changes in SBP and DBP were SBP: -3.13 (95% CI: -3.93– -2.32)  
  DBP: -2.00 (95% CI: -2.65– -1.35).  
- In meta-regression analysis, there was a strong relationship between the extent of BP reduction and change in BP, with no reduction in BP for those consuming 2 or less drinks at baseline but increasing reductions in BP for those with progressively higher intakes of alcohol at baseline. For instance, in those consuming ≥6 drinks/day and reducing their alcohol intake by approximately 50%, the estimated reduction in SBP and DBP were:  
  SBP: -5.5 (95% CI: -6.70– -4.30)  
  DBP: -3.97 (95% CI: -4.70– -3.25). Similar patterns of the effect of baseline alcohol intake on treatment effect were noted for a variety of subgroups.  

**1° Safety endpoint:** N/A
## Data Supplement 17. RCTs and Meta-analysis RCTs Studying the Effect of Nonpharmacologic Interventions on BP (Calcium Supplementation) (Section 6.2)

<table>
<thead>
<tr>
<th>Study Acronym; Author; Year Published</th>
<th>Aim: Study the effect of calcium supplementation on BP</th>
<th>Study Type: Systematic review and meta-analysis</th>
<th>Size:</th>
<th>Inclusion criteria:</th>
<th>Intervention: increased calcium intake, with a range from 355–2,000 mg/d (mean=1,200 mg/d; median=1,055 mg/d), primarily as a gluconate or carbonate salt.</th>
<th>Comparator: Placebo or usual intake – 32 double-blind.</th>
<th>Endpoint Results (Absolute Event Rates, P value; OR or RR; &amp; 95% CI): 1° endpoint: Overall, increased calcium intake was associated with a significant reduction in mean SBP of -1.86 (95% CI: -2.91– -0.81) and DBP of -0.99 (95% CI: -1.61– -0.37). The reduction was slightly less but still significant in the subset of 32 double-blind trials, with a mean SBP of -1.67 (95% CI: -2.87– -0.47) and DBP of -0.93 (95% CI: -1.64– -0.22). There was no significant difference between the effect size in those with a baseline BP ≥ or &lt;140/90 mm Hg. The mean change in SBP and DBP for those with a baseline BP≥140/90 mm Hg (23 comparisons) was -2.17 (95% CI: -3.78– -0.55) and -0.95 (95% CI: -1.89– -0.01), respectively. The mean in SBP and DBP for those with a baseline BP&lt;140/90 mm Hg was -1.67 (95% CI: -3.01– -0.27) and -1.02 (95% CI: -1.85– -0.19) mm Hg, respectively. The authors reported slightly larger effect sizes in those with a lower initial calcium intake, in trials that employed a dietary</th>
<th>Relevant 2° Endpoint (if any); Study Limitations; Adverse Events: This is the most recent SR/MA on this topic to include RCT conducted in both normotensive and hypertensive pts. The authors interpreted their results as being consistent with a beneficial effect of calcium supplementation on BP, with about a 2 mm Hg reduction in SBP for a 1 g increase in calcium intake. This is slightly larger effect size than noted in several earlier meta-analyses. A subsequent Cochrane Collaboration meta-analysis was confined to 13 RCT in 485 adults (≥18 y) with HTN studied for ≥8 wk (Dickinson HO et al. Cochrane Database of Systematic Reviews. 2006; CD004639). The authors noted a significant reduction in mean of -2.5 (95% CI: -4.5– -0.6) for SBP but a more modest insignificant change of -0.8 (95% CI: -2.1– 0.4) for DBP. Due to the poor quality of the RCT and heterogeneity of the results, the authors concluded the reduction in SBP was likely an artifact due to bias. Although not included in most meta-analyses, calcium supplementation has been effective as a treatment in pregnant women at risk for pre-eclampsia. Several of the meta-analyses (including the 1 by van Mierlo et al) have suggested a bigger effect size in persons with a lower intake of calcium at baseline and in trials that utilized a dietary intervention.</th>

</table>
| Whelton SP, et al., 2002 (96) 11926784 | Aim: Study the effect of aerobic exercise on BP  
Study type: Systematic review and meta-analysis  
Size: 38 reports (54 comparisons) with 2,419 pts; 27 of the comparisons were conducted in normotensive pts | Inclusion criteria:  
• English language publication between 1966–2001  
• RCT in adults ≥18 y  
• Duration ≥2 wk  
• No concurrent interventions  
Exclusion criteria: Missing BP data | Intervention: Aerobic exercise  
Comparator: No exercise prescribed | 1° endpoint:  
• For the overall group, a pooled analysis of experience in 53 trials identified a mean net change in SBP of -3.84 (95% CI: -4.97– -2.72). In subgroup analysis, the effect was noted in different ethnic groups, in trials that employed different designs, durations, and sample sizes, in trials with obese, overweight or normal weight pts, and in trials that employed different types, intensity levels, and duration of aerobic exercise.  
• In the subgroup of 15 trials in hypertensives, the mean net change in SBP was -4.94 (95% CI: -7.17– -2.70).  
1° Safety endpoint: N/A  
Most of the trials were of short duration and did not (have the capacity) report on potential adverse effects such renal stones.  
In addition to being small, several trials were of uncertain quality.  
Overall, RCT experience provides limited and inconsistent evidence from trials of variable quality in support of calcium supplementation for prevention (or treatment) of HTN. Better evidence supports the role of calcium supplements, in conjunction with vitamin D, in strengthening bone density. | This meta-analysis provides the most comprehensive analysis of the effect of aerobic exercise on BP and provides strong evidence in support of aerobic exercise as an intervention to lower BP in normotensives.  
Recognizing this, many of the trials were small and of short duration. |
| **Cornelissen VA, et al., 2013 (97)** 23525435 | **Aim:** Study the effect of different types of physical activity on BP  
- Dynamic aerobic endurance  
- Resistance training  
- Dynamic  
- Static (Isometric)  
**Study type:** Systematic review and meta-analysis  
**Size:** Overall, 93 studies (>5,000 pts)  
- 59 Dynamic Aerobic Endurance studies  
- 13 Dynamic Resistance Training studies  
- 5 Combined Dynamic Aerobic and Resistance training  
- 4 Static (Isometric) Resistance  
- 12 Different interventions within 1 trial | **Inclusion criteria:**  
- Parallel arm RCTs  
- Adults≥18 y  
- Peer reviewed journals up to February 2012  
- Trial duration ≥4 wk  
**Exclusion criteria:** Inadequate reporting of the data | **Intervention:** Physical activity  
**Comparator:** No prescription of physical activity | • In the subgroup of 27 trials conducted in normotensives, the mean net change in SBP was -4.04 (95% CI: -5.32– -2.75).  
**1st Safety endpoint:** N/A  
• Most recent in a series of progressively updated publications from Dr. Cornelissen and her colleagues.  
• The findings suggest a beneficial effect of all forms of physical activity on BP, with a disproportionately large effect of resistance training on BP.  
• Many of the available RCTs have been small, of short duration, and of uncertain quality. |
| **Rossi AM, et al., 2013 (98)** 23541664 | **Aim:** Study the effect of resistance exercise on BP  
**Study type:** Systematic review and meta-analysis | **Inclusion criteria:**  
- RCTs in adults (≥18 y)  
- BP-lowering 1st outcome  
**Intervention:** Dynamic resistance training but overall reporting of the details was poor. | **1st endpoint:** Overall (trials in hypertensives and normotensive), pooled experience identified a significant reduction in BP with all forms of physical activity (aerobic and both forms of resistance training), with mean reductions in SBP of -3.5 mm Hg following aerobic endurance training, 1.8 mm Hg following dynamic resistance training, and -10.9 mm Hg following static (isometric) resistance training (p<0.001 for the difference between the effect size following static [isometric] and other forms of physical activity). In subgroup analysis, dynamic aerobic endurance and dynamic resistance training resulted in mean SBP changes of -2.1 (95% CI: -3.3– -0.83) and -4.3 (95% CI: -7.7– -0.90), respectively, in the pts with pre-HTN and smaller, nonsignificant reductions in the remaining pts with a normal BP.  
**Safety endpoint:** N/A  
• Suggests resistance training is effective in lowering BP and was the basis for recommending this intervention in the Canadian HTN Education Program recommendations. |

| Carlson DJ, et al., 2014 (100) 24582191 | **Aim:** Study the effect of physical activity on BP in children with obesity.  **Study type:** Systematic review and meta-analysis.  **Size:** 9 RCTs (223 pts: 127 intervention and 96 controls): 6 were conducted in normotensives. | **Inclusion criteria:**  - Adults ≥18 y  - RCT, including cross-over trials.  - Duration ≥4 wk  - Published in a peer reviewed journal between January 1, 1966 and July 31, 2013  - Studies that employed any intervention other | **Comparator:** Use of a control group was a requirement but no additional specific information provided. | **1° endpoint:**  - In the overall pooled analysis (hypertensive and normotensive trials), mean change in SBP was -6.77 (95% CI: -7.93 – -5.62) mm Hg.  - In the subgroup of 3 trials with hypertensive pts (all on antihypertensive medication), the mean change in SBP was -4.31 (95% CI: -6.42 – -2.21) mm Hg.  - In the subgroup of 6 trials with normotensive pts, the mean change in SBP was -7.83 (95% CI: -9.21 – -6.45) mm Hg. | **Notes:**  - This study provides information regarding the effect of pure isometric exercise interventions on BP in adults.  - The BP reductions reported in this meta-analysis are surprisingly large but the overall effect pattern is quite consistent with other meta-analyses of isometric exercise. |  

|  | **Size:** 9 RCTs (11 intervention groups and 14 comparisons) conducted in 452 pts. 10 (71%) of the 14 comparisons were conducted in normotensives  | **Trial duration ≥4 wk**  - Resistance training only intervention | **Comparator:** No resistance training but not detailed in this article | for DBP was -2.19 (95% CI: -3.87 – -0.51).  **Safety endpoint:** N/A |  |  

- Trial duration ≥4 wk
- Resistance training only intervention
- **Comparator:** No resistance training but not detailed in this article
- **Exclusion criteria:** Handgrip/isometric exercise
- **Comparator:** No resistance training but not detailed in this article for DBP was -2.19 (95% CI: -3.87 – -0.51).
- **Safety endpoint:** N/A
- The discrepancy in effect size between this meta-analysis and the 1 conducted by Cornelisson et al may have been due to the more restrictive requirement by Rossi et al that change in BP be the 1° outcome.
- This meta-analysis focused specifically on the effect of physical activity on BP in children with obesity. Although it is not stated explicitly, it seems likely that all of the participants were normotensive and not receiving medication that could influence level of BP.
- The findings are consistent with other meta-analyses of the effect of physical activity on BP.
- Only limited information regarding study details is provided in this publication. The interventions were heterogeneous in type, duration, and quality.
- This study provides information regarding the effect of pure isometric exercise interventions on BP in adults.
- The BP reductions reported in this meta-analysis are surprisingly large but the overall effect pattern is quite consistent with other meta-analyses of isometric exercise.
Cornelissen VA, et al., 2011 (101) 21896934

Aim: Study the effect of resistance training on BP.

Study type: Meta-analysis

Size: 28 randomized, controlled trials, involving 33 study groups and 1,012 pts.

Inclusion criteria: • Adults ≥18 y • RCT, including cross-over trials. • Duration ≥4 wk • Published in a peer reviewed journal up to June 2010

Exclusion criteria: Interventions other than pure isometric exercise (e.g. dynamic resistance)

Intervention: Resistance training, including isometric and dynamic modalities.

Comparator: Use of a control group was a requirement but no additional specific information provided.

1° endpoint: Resistance training induced a significant SBP/DBP reduction in 28 normotensive or prehypertensive study groups of -3.9 (-6.4, -1.2) / -3.9 (-5.6, -2.2) mm Hg. In the 5 hypertensive study groups, the change in mean SBP/DBP was -4.1 (95% CI: -0.63–1.4) / 1.5 (95% CI: -3.4–0.40) mm Hg. When the study groups were divided according to the mode of training, isometric handgrip training in 3 groups resulted in a larger decrease in SBP/DBP (-13.5 [95% CI: -16.5– -10.5] / -6.1 [95% CI: -8.3– -3.9] mm Hg) than dynamic resistance training in 30 groups (-2.8 [95% CI: -4.3– -1.3] / -2.7 [95% CI: -3.8– -1.7] mm Hg).

Safety endpoint: N/A

● This meta-analysis supports the BP-lowering potential of dynamic resistance training and isometric handgrip training.
● Results further suggest that isometric handgrip training may be more effective for reducing BP than dynamic resistance training.
● However, given the small amount of isometric studies available, additional studies are warranted to confirm this finding.

Data Supplement 19. RCTs and Meta-analysis RCTs Studying the Effect of Nonpharmacologic Interventions on BP (Magnesium Supplementation) (Section 6.2)

Kass L, et al., 2012 (102) 22318649

Aim: Study the effect of magnesium supplementation on BP

Study type: Systematic review and meta-analysis

Inclusion criteria: • RCT in humans • Parallel or cross-over design • Publication before July 2010 • Adults >18 y • Only difference between the

Intervention: Increased magnesium intake, with a range in elemental magnesium of 120 to 973 mg/d and a mean of 410 mg/d.

Comparator: Placebo or usual intake

1° endpoint: Overall, increased magnesium intake was associated with a small nonsignificant reduction in mean SBP of -0.32 (95% CI: -0.41– -0.23) and DBP of -0.36 (95% CI: -0.44– -0.27).

● This is the most recent systematic review/meta-analysis on this topic. The authors interpreted their results as being consistent with a beneficial effect of magnesium supplementation on BP. However, this interpretation seems at odds with the data.
● In an earlier meta-analysis of 20 RCT (6 in normotensives) by Jee Systolic
Size: 22 RCTs (23 comparisons) with 1,173 pts. Data for RCTs conducted in normotensive pts were not presented. However, most RCTs were conducted in normotensives and only 6 of the RCTs included some (or all) pts who were being treated with antihypertensive medication. Overall mean age was ~50 y. Follow-up varied from 3–24 wk, with a mean of 11.3 wk.

**Exclusion criteria:** Comparison of different doses of alcohol intake

- Forest plots revealed considerable heterogeneity in effect size.
- The authors reported slightly larger effect sizes in subgroup analysis of cross-over RCT and RCT that employed a dose of magnesium >370 mg/d.

1° Safety endpoint: N/A

HTN et al (Am J Hypert. 2002;15:691-696) magnesium supplementation resulted in small mean NS reductions of -0.6 (95% CI: -2.2–1.0) mm Hg in SBP and -0.8 (95% CI: -1.9–0.4) in DBP. In meta-regression analysis, there was an apparent dose-response with SBP and DBP reductions of -4.3 (95% CI: -6.3–-2.2) and -2.3 (95% CI: -4.9–0) mm Hg for each 10 mmol/d higher level of magnesium intake.

- A Cochrane systematic review/meta-analysis of magnesium supplementation for treatment of HTN in adults (Dickinson HO et al. Cochrane Database Systematic Review 2006: CD 004640) included 12 RCT (n=545) with follow-up of 8–26 wk. Overall, mean SBP and DBP were reduced by -1.3 (95% CI: -4.0–1.5) and -2.2 (95% CI: -3.4–-0.9) mm Hg, respectively. The authors noted the studies were of poor quality, with considerable heterogeneity, and felt the results were likely biased.
- Some authors have suggested there may be a greater BP effect when the intervention is by means of diet change but there is insufficient RCT evidence to support this position.
- Magnesium sulfate is the drug of choice for prevention of seizures in the pre-eclamptic woman, or prevention of recurrence of seizures in the eclamptic woman, as demonstrated in RCT and a 2010 Cochrane review (Duley L et al. Cochrane Database of Systematic Reviews. CD000127, 2010).
- Overall, RCT experience provides insufficient evidence to recommend oral
magnesium supplementation as a means to prevent (or treat) HTN.

Data Supplement 20. RCTs Studying the Effect of Nonpharmacologic Interventions on BP (Weight Loss) (Section 6.2)

<table>

| Neter JE, et al., 2003 (103) 12975389 | **Aim:** Study the effect of weight loss on BP  
**Study type:** Systematic review and meta-analysis  
**Size:** 25 RCTs (34 comparisons) with 4,874 pts; 17 of the comparisons were conducted in normotensive pts  
**Inclusion criteria:**  
- RCT in humans  
- English language publication between 1966–2002  
- Nonpharmacologic intervention  
**Exclusion criteria:**  
- Duration <8 wk  
- Missing data  
- Objective not weight loss  
- Concomitant intervention(s)  
**Intervention:** Weight loss (calorie reduction, physical activity, or combination of both)  
**Comparator:** No weight loss prescription  
**1° endpoint:**  
- For the overall group, mean baseline body weight was 88.3 kg and mean change in body weight following the application of the weight loss intervention was -5.1 (95% CI: -6.03– -4.25) kg. This represents a mean percent change of -5.8%.  
- There was strong evidence for a BP lowering effect of weight loss on BP, overall and in normotensive subgroup. In the normotensive group, the mean for change in SBP was 4.08 (95% CI: -6.01– -2.16).  
- Overall, a 1 kg reduction in body weight was associated with a mean change in SBP of -1.05 (95% CI: -1.43– -0.66) mm Hg.  
**1° Safety endpoint:** N/A  
**• Substantial evidence for a reduction in BP, overall and in normotensives.**  
**• With the exception of the mean (95% CI) changes in BP, this paper provides limited data for the normotensive group.** |
| Ho M, et al., 2012 (104) 23166346 | **Aim:** Study the effect of lifestyle weight loss interventions in obese/overweight children on weight  
**Inclusion criteria:**  
- RCTs, in obese/overweight children and adolescents ≤18 y  
**Intervention:** Lifestyle weight loss program with a dietary component  
**Comparator:** No treatment, usual care or  
**1° endpoint:** Pooled experience in the 7 RCTs with BP experience identified a significant reduction in mean SBP of -3.40 (95% CI: -5.19– -1.61). The pooled SBP MD was -3.72 (95% CI: -4.74– -2.69) in the 3 RCTs with a duration >1 y  
**• Findings in children are consistent with experience in adult normotensives and with experience in hypertensive pts.** |

## Data Supplement 22. Observational Studies of CV Target Organ Damage Including LVH (Section 7.2)

<table>
<thead>
<tr>
<th>Study Acronym; Author; Year Published</th>
<th>Study Type/Design; Study Size (N)</th>
<th>Patient Population</th>
<th>Primary Endpoint and Results (include P value; OR or RR; &amp; 95% CI)</th>
<th>Summary/Conclusion Comment(s)</th>
</tr>
</thead>
</table>
| **LIFE** Devereux RB, et al., 2004 (108) 15547162 | Study type: Sub-study of pts with HTN and ECG LVH  
Size: 941 | Inclusion criteria:  
- 55–80 y  
- BP 160–200/95–115 mm Hg  
- No MI or stroke within 6 mo  
- Had echo  
- Did not require treatment with BB, ACE or AT-1 antagonist for other reasons  
Intervention: Treatment to BP of 140/90 mm Hg beginning with pts randomized to losartan or atenolol | 1st endpoint: Change in LV mass assessed by echo and change in BP in relation to CVD events  
Results:  
- Composite endpoint of CV death, MI, or stroke reached in 104 in 4.8 y of follow-up  
- Reduction in 1st endpoint per SD reduction in LV mass independent of BP change OR: 0.74 (95% CI: 0.6–0.91; p=0.003)  
- Reductions for each composite endpoint component and total mortality were also significant; results independent of change in ECG LVH | Reduction in LV mass by echo independently related to CVD outcomes |
| **CARDIA** Armstrong AC, et al., 2014 (109) 24507735 | Study type: Observational study of population-based cohorts | Inclusion criteria: African American and white men and women stratified by education (above/below high school) 18–30 y at study start and followed for over 20 y; previously healthy | 1st endpoint: Composite of hard CVD events  
Results:  
- LV mass indexed to body surface area or to height predicted CV events independently of the Framingham risk score (HR: 1.21; 95% CI: 1.05–1.39; p<0.007) | LV mass measured at age 18–30 y leads to modest risk reclassification later in life  
Low number of events limits generalizability |
### ARIC
Okwuosa TM, et al., 2015 (110) 25497261

**Study type:** Observational study of population-based cohorts  
**Size:** 14,489

**Inclusion criteria:** African American and white men and women population-based cohort mean age 54.7 ± 5.7 y at study start and followed for over 25 y; previously healthy

**1° endpoint:** Pooled cohort CV events and 10-y Framingham CVD events

**Results:**  
- 792 (5.5%) 10-y Pooled Cohort CV events and 690 (4.8%) 10-y Framingham CHD events.  
- LVH was associated with CVD events (HR: 1.62; 95% CI: 1.38–1.90) and CHD events (HR: 1.56; 95% CIL 1.32–1.86.  
- LVH by ECG did not significantly reclassify or improve C statistic compared with Framingham risk score (C statistics 0.767/0.719; net reclassification index =0.001 [p=not significant]), compared with (C statistics 0.770/0.718), respectively.

**Summary:**  
- ECG LVH does not improve risk reclassification

### MESA
Zalawadiya SK, et al., 2015 (111) 24699336

**Study type:** Observational study of population-based cohorts  
**Size:** 4,921

**Inclusion criteria:** Multi-ethnic cohort of men and women followed for a mean follow-up of 4.5 y

**1° endpoint:** Hard CVD endpoints

**Results:** MRI calculated LVH (indexed to BSA or height; >95th percentile) predicted hard CVD events (LVH-BSA: HR: 2.36; 95% CI: 1.37–4.04; p=0.002; LVH-height [1.7]: HR: 1.95; 95% CI: 1.17–3.26; p=0.01), but did not improve risk reclassification beyond conventional risk factors

**Summary:**  
- Though LVH predicted events it did not improve risk reclassification

---

- **Study type:** Meta-analysis of RCTs

- **Size:** 10 RTCs with 15,266 pts

- **Inclusion criteria:** RCTs of at least 1 y duration; pts ≥18 y, at least 80% of whom had grade 1 HTN and no previous CVD (MI, angina pectoris, CABG, PCI, stroke, TIA, carotid surgery, peripheral arterial surgery, intermittent claudication, or renal failure); and compared an antihypertensive drug provided as monotherapy or a stepped-care algorithm vs. placebo or another control regimen.

- **Intervention:** BP-lowering meds

- **Comparator:** Placebo or less intensive treatment

- **1st endpoint:** Total major CV events, comprising stroke (nonfatal stroke or death from cerebrovascular disease), coronary events (nonfatal MI or death from CHD, including sudden death), HF (causing death or resulting in hospitalization), or CV death; OR: 0.86 (95% CI: 0.74–1.01)

- **Other endpoints:** Each of the above outcomes independently; and total deaths.

- **Summary:** BP-lowering therapy is likely to prevent stroke and death in pts with uncomplicated grade 1 HTN.

- **5 y risks in BPLTTTC control groups CVD events 7.4% CVD deaths 3.1%
Thompson AM, et al., 2011 (113) 21364140

**Aim:** To evaluate the effect of antihypertensive treatment on 2° prevention of CVD events and all-cause mortality among pts without clinically defined HTN.

**Study type:** Meta-analysis of RCTs

**Size:** 25 RCTs with 64,162 pts

**Inclusion criteria:** Studies were eligible for inclusion if they were RCTs of antihypertensive treatment among pts with BP <140 mm Hg systolic or <90 mm Hg diastolic for the prevention of CVD events (fatal or nonfatal stroke, fatal or nonfatal MI, CHF, or CVD mortality).

**Exclusion criteria:** Studies were excluded if CVD events were not reported by HTN status in studies that included pts with and without HTN; the study population did not include pts with BP in the normal or prehypertensive ranges; the study population did not include pts with preexisting CVD or CVD equivalents, such as diabetes; antihypertensive treatment was not part of the intervention; treatment allocation was not random; a measure of variance (p-value or CI) was not reported or could not be calculated from the information provided; pts <18 y; or there were differences between groups.

**Intervention:** BP-lowering meds, the majority were studies of ACEI, next most common were BBs.

**Comparator:** Placebo or active comparator

**1° endpoint:**
- Composite CVD (fatal or nonfatal stroke, fatal or nonfatal MI, CHF, or CVD mortality):
  - CVD RR: 0.85 (95% CI: 0.80–0.90), absolute risk reduction: 27.1/1,000.
  - This implies that a 2.7% absolute risk reduction reflects a 15% RR reduction, so the baseline risk for CVD would have been about 18%, but the follow-up interval is unclear.

**Other endpoints:**
- Stroke RR: 0.77 (95% CI: 0.61, 0.98)
- MI RR: 0.80 (95% CI: 0.69, 0.93)
- HF RR: 0.71 (95% CI: 0.65, 0.77)
- CVD death RR: 0.83 (95% CI: 0.69, 0.99)
- Total deaths RR: 0.87 (95% CI: 0.80, 0.95)

**Other results:** Table 4 shows similar results for CVD from studies of pts with CAD vs. other, HF vs. other, and DM vs. non-DM. Similar results from studies of ACEI vs. other. These results support the Summary: Among pts with clinical history of CVD but without HTN, antihypertensive treatment was associated with decreased risk of stroke, CHF, composite CVD events, and all-cause mortality.

**Limitations:**
- Difference in achieved BP was not reported.
- Average baseline SBP not reported. No information on the entry levels of BP other than not hypertensive. Difficult to use to establish a treatment threshold or goal.
- Many of these studies were designed to try to demonstrate specific drug benefits rather than BP-lowering benefits. Can we attribute the benefits to BP-lowering? We know these pts did not have HTN but we do not know the lower limit of the BP inclusion ranges or the treatment associated difference in SBP between groups making it difficult to

<td>Intensive BP-lowering, including to &lt;130 mm Hg, provided greater vascular protection than standard regimens. In high-risk pts, there are additional benefits from more intensive BP-lowering, including for those with SPB &lt;140 mm Hg at baseline. The net absolute benefits of intensive BP-lowering in high-risk individuals are large.</td>
</tr>
</tbody>
</table>

Limitations: <br> • Lack of individual pt data, which would have allowed a more reliable assessment of treatment effects in different pt groups. <br> • Interpretation: Supports treating pt with and without CVD at threshold of 130 to <130. Supports treating at threshold of about 130 even down to a CVD event rate of 0.9% per y.

Intervention and control groups other than antihypertensive treatment. Conclusion that the effect is not a drug effect, but is a BP-lowering effect, and that the effect is seen in people with CVD broadly defined, not just in HF pts. Establish a treatment initiation threshold or goal.
**Aim:** This systematic review and meta-analysis aims to combine data from all published large-scale BP-lowering trials to quantify the effects of BP reduction on CV outcomes and death across various baseline BP levels, major comorbidities, and different pharmacological interventions.

**Inclusion criteria:**
- RCTs of BP-lowering treatment that included a minimum of 1,000 pt-y of follow-up in each study arm. No trials were excluded because of presence of baseline comorbidities, and trials of antihypertensive drugs for indications other than HTN were eligible.
- Eligible studies fell into 3 categories: 1st, random allocation of pts to a BP-lowering drug or placebo; 2nd, random allocation of pts to different BP-lowering meds

**Comparator:** Placebo, active comparator or less intensive treatment

**Intervention:** BP-lowering meds

**1° endpoint:**
- CVD,
- Major CVD events, CHD, stroke, HF, renal failure, and all-cause mortality.

- Standardized RR for 10 mm Hg difference in SBP
- CVD RR: 0.80 (95% CI: 0.77–0.83)

**Other endpoints:**
- CHD RR: 0.83 (95% CI: 0.78–0.88)
- Stroke RR: 0.73 (95% CI: 0.68–0.77)

**Summary:**
- BP-lowering significantly reduces vascular risk across various baseline BP levels and comorbidities. Our results provide strong support for lowering BP to SBP <130 mm Hg and providing BP-lowering treatment to individuals with a history of CVD, CHD, stroke, DM, HF, and CKD.
- In stratified analyses, we saw no strong evidence that proportional effects were diminished in trials that included people with lower...
**Study type:** Meta-analysis of RCTs

**Size:** 123 studies with 613,815 pts

**Exclusion criteria:** <1,000 pt-y of follow-up in each treatment group.

- HF RR: 0.72 (95% CI: 0.67–0.78)
- Total deaths RR: 0.87 (95% CI: 0.84–0.91)

**Other results:**
- Benefit for CVD and other endpoints not different by baseline SBP, including <130 mm Hg fig 4 in paper
  - CVD: 0.63; 95% CI: 0.50–0.80; p=0.22
  - CHD: 0.55; 95% CI: 0.42–0.72; p=0.93
  - Stroke: 0.65; 95% CI: 0.27–1.57; p=0.38
  - HF: 0.83; 95% CI: 0.41–1.70; p=0.27
  - Total deaths: 0.53; 95% CI: 0.37–0.76; p=0.79
- More precision around estimates of benefits in SBP 130–139 at baseline, fig 4 in paper
- Results similar in trials of people with and without CVD at baseline figure 5
  - CVD+ 0.77 (95% CI: 0.71–0.81)
  - CVD+ 0.74 (95% CI: 0.67–0.83)
  - Total deaths
  - CVD+ 0.90 (95% CI: 0.83–0.98)
  - CVD+ 0.84 (95% CI: 0.75–0.93)

**Baseline SBP (<130 mm Hg), and major CV events were clearly reduced in high-risk pts with various baseline comorbidities. Both of these major findings—the efficacy of BP-lowering below 130 mm Hg and the similar proportional effects in high risk populations—are consistent with and extend the findings of the SPRINT trial.**

**Limitations:**
- Lack of individual pt data, which would have allowed a more reliable assessment of treatment effects in different pt groups.
- Interpretation: Lowering of BP into what has been regarded the normotensive range should therefore be routinely considered for the prevention of CVD among those deemed to be of sufficient absolute risk.
### SPRINT

**Wright JT Jr, et al., 2015**

**Aim:** To test the effectiveness of a goal SBP<120 mm Hg vs. a goal SBP<140 mm Hg for the prevention of CVD in pts with SBP≥130 mm Hg at baseline.

**Study type:** RCT

**Size:** 9361 pts followed median of 3.26 y.

**Inclusion criteria:** SBP≥130 mm Hg, with upper limit varying as number of pre-trial BP-lowering meds increased. Presence of at least 1 of the following:
- Clinical or subclinical CVD
- CKD stage ≥3
- Age≥75
- Framingham General CVD risk≥15% in 10 y

**Exclusion criteria:** DM, history of stroke, ESRD (eGFR <20)

**Intervention:** Intensive BP-lowering treatment to goal SBP <120 mm Hg

**Comparison:**
- Standard BP-lowering treatment to goal SBP<140 mm Hg
- Net treatment difference ~3 drugs (2.8) on average vs. 2 drugs (1.8) on average
- During the trial, mean SBP was 121.5 vs. 134.6.

**1° endpoint:** CVD (MI, ACS, stroke, HF, CVD death)

HR: 0.75 (95% CI: 0.64, 0.89)

**Other endpoints:**
- Total deaths HR: 0.73 (95% CI: 0.60–0.90)
- 1° or death HR: 0.78 (95% CI: 0.67–0.90)
- Components of 1° composite mostly consistent in direction other than ACS – no difference.

**CKD outcomes:**
- 1° in CKD pts: reduction in GFR of ≥50% or ESRD HR: 0.89 (95% CI: 0.42, 1.87)
- Incident albuminuria HR: 0.72 (95% 0.48, 1.07)
- In pts without CKD: reduction in GFR ≥30% and to <60
  - HR: 3.49 (95% CI: 2.44–5.10)
- Incident albuminuria HR: 0.81 (95% CI: 0.63–1.04)

**Adverse events:**
- SAEs: 1.04; p=0.25
- Significant absolute increases seen in intensive group for hypotension (1%), syncope (0.6%), electrolyte abnormality (0.8%), acute kidney injury/acute renal failure (1.6%) over the study period.

**Summary:**
- More intensive SBP lowering to a goal of <120 mm Hg with achieved mean of approximately 121 mm Hg resulted in less CVD and lower total mortality over 3.26 y in comparison with a goal SBP <140 mm Hg and achieved SBP of ~135 mm Hg.
- There were small increases in some expected SAEs. Perhaps unexpected, a sizable increase in reduced eGFR in the non-CKD group and AKI/ARF overall was observed in the intensive group. While of uncertain etiology and significance, there is speculation this could be an acute hemodynamic effect, especially given the findings regarding albuminuria.

**Limitations:** Few pts were untreated at baseline ~9%, so SPRINT provides little if any insight at present regarding BP-lowering medication initiation for untreated people with SBP 130–139.

<tr>
<td><strong>Aim:</strong> To determine the quantitative efficacy of different classes of BP-lowering drugs in preventing CHD and stroke, and who should receive treatment. 5 questions encapsulate this uncertainty. 1st, do BBs have a special effect over and above lowering BP in preventing CHD events in people with a history of CHD? 2nd, does the effect of BP-lowering drugs in preventing CHD and stroke differ in people with and without a history of CVD? 3rd, does BP reduction alone explain the effect of BP-lowering drugs in preventing CHD and stroke? 4th, should the use of BP-lowering drugs be limited to people with high BP and not given to those at high risk of CVD? 5th, should the use of BP-lowering drugs be extended to people at moderate risk of CVD?</td>
</tr>
<tr>
<td><strong>Inclusion criteria:</strong> The database search (by MRL) used Medline (1966 to December 2007; any language) to identify randomized trials of BP-lowering drugs in which CHD events or strokes were recorded (irrespective of whether BP reduction was considered the mechanism of action). Search terms were “antihypertensive agents” or “HTN” or “diuretics, thiazide” or “adrenergic beta-antagonists” or “angiotensin-converting enzyme inhibitors” or “receptors, angiotensin/antagonists &amp; inhibitors” or “tetrazoles” or “CCB’s” or “vasodilator agents” or the names of all BP-lowering drugs listed in the British National Formulary as keywords or text words. Limits were Medline publication type “clinical trial” or “controlled clinical trial” or “RCT” or “meta-analysis”. We also searched the Cochrane Collaboration and Web of Science databases and the citations in trials and previous meta-analysis and review articles.</td>
</tr>
<tr>
<td><strong>Exclusion criteria:</strong> We excluded nonrandomized trials and trials in which treated groups but not control groups</td>
</tr>
<tr>
<td><strong>Intervention:</strong> BP-lowering medications</td>
</tr>
<tr>
<td><strong>Comparison:</strong> Placebo or less intensive treatment</td>
</tr>
<tr>
<td><strong>1st endpoint:</strong> CHD and stroke co-1st Standardized to a 10/5 mm Hg BP reduction Overall CHD: 0.78 (95% CI: 0.73–0.83) Stroke: 0.59 (95% CI: 0.52–0.67) In absence of vascular disease CHD: 0.79 (95% CI: 0.72–0.86) Stroke: 0.54 (95% CI: 0.45–0.65) History of CHD CHD: 0.76 (95% CI: 0.68–0.86) Stroke: 0.65 (95% CI: 0.53–0.80) History of stroke CHD: 0.79 (95% CI: 0.62–1.00) Stroke: 0.66 (95% CI: 0.56–0.79) No big drug class effects except more benefit for BBs shortly after MI. Treatment benefits seen down to pre-treatment SBP of 110–119 mm Hg for CHD events RR: 0.78 (95% CI: 0.63–0.96) and 130–139 mm Hg for stroke RR: 0.75 (95% CI: 0.63–0.89)</td>
</tr>
<tr>
<td><strong>Summary:</strong> The effect of BP-lowering drugs in reducing the risk of disease is entirely or largely due to BP reduction, with 1 main exception, a special extra effect of BBs in people who have had a recent MI. The proportional reduction in CHD events and stroke for a given reduction in BP, an approximate halving in risk for each 10 mm Hg diastolic reduction, is the same in people with and without a history of vascular disease and in people without high BP as well as in those with high BP. There is benefit in lowering BP in anyone at sufficient CV risk whatever their BP, so avoiding the need to measure BP routinely.</td>
</tr>
<tr>
<td><strong>Limitation:</strong> Most of the pts without HTN were in the trials of people with pre-existing CVD; hence, most of the results of BP lowering in people with SBP&lt;140 are in people with CVD. No absolute risks or benefits provided. Not possible to estimate how far down the risk curve these results apply.</td>
</tr>
</tbody>
</table>
| **Interpretation:** This MA provides stronger support for
who have a lower BP? A corollary is whether BP should be reduced to a limited extent only, a treat to target approach. Although cohort (prospective/observational) studies do not show a lower BP limit below which risk ceases to decline (“the lower the better”), this has not been shown in randomized trials across a wide range of BP. Finally, what is the quantitative effect of taking ≥1 BP-lowering drugs in lowering BP and preventing CHD events and stroke according to dose, pretreatment BP, and age? To date no such quantitative summary of effect, taking account of these determining factors, has been made.

**Study type:** Meta-analysis of RCTs

**Size:** 147 RCTs of BP-lowering meds and CHD events (22,000) and stroke (12,000).

had other interventions as well as BP reduction, such as cholesterol reduction. We excluded trials in pts with chronic renal failure because these pts typically have high BP and high rates of CVD and their response to standard BP-lowering therapy may differ from other people. We also excluded trials in which fewer than 5 CHD events and strokes were recorded or the duration of treatment was less than 6 mo, as these data would contribute little to the overall results and substantially increase the complexity of the analyses. RCTs were otherwise included irrespective of pt age, disease status, BP before treatment, or use of other drugs.

| treating at levels <140 for people with CVD than for people without CVD. |  |  |  |
| Lewington S, et al., 2002 (16) 12493255 | **Aim:** To describe the age-specific relevance of BP to cause-specific mortality  
**Study type:** Meta-analysis of cohort studies  
**Size:** 61 prospective studies with 12.7 million person-y of observation, 56,000 vascular deaths in 40–89 y. | **Inclusion criteria:** Collaboration was sought from the investigators of all prospective observational studies in which data on BP, blood cholesterol, date of birth (or age), and sex had been recorded at a baseline screening visit, and in which cause and date of death (or age at death) had been routinely sought for all screens during more than 5,000 person-y of follow-up (see appendix A; http://image.thelancet.com/extra/s01art8300webappendixA.pdf). Relevant studies were identified through computer searches of Medline and Embase, by hand-searches of meeting abstracts, and by extensive discussions with investigators.  
**Exclusion criteria:** To minimize the effects of reverse causality (whereby established disease could change the usual BP), studies were excluded if they had selected pts on the basis of a positive history of stroke or heart disease, and individuals from contributing studies were excluded from the present analyses if they had such a history recorded at baseline. | **Intervention:** N/A  
**Comparator:** N/A  
- The exposures of interest were the level of SBP and DBP and age-group. | **1° endpoint:**  
- Not completely clear, but for our purposes, stroke and IHD death would be co-1°. Also looked at other vascular deaths.  
- HRs for stroke mortality for a 20 mm Hg lower SBP by age-group  
  40–49: 0.36 (95% CI: 0.32–0.40)

- with placebo over baseline antihypertensive treatment, resulting in a BP difference of at least 2 mm Hg in either SBP or DBP (nonintentional BP-lowering trials); enrolling of hypertensive individuals only or a high proportion (at least 40%) of them.

- **Exclusion criteria:** N/A

- (intentional BP-lowering trials), or comparison of an active drug with placebo over baseline antihypertensive treatment, resulting in a BP difference of at least 2 mm Hg in either SBP or DBP (nonintentional BP-lowering trials); enrolling of hypertensive individuals only or a high proportion (at least 40%) of them. Other inclusion criteria can be found in the preceding paper. 51 trials were found eligible either for assessing BP-lowering effects in different HTN grades or for assessing the effects of achieving different BP levels

- trials or trial subgroups with mean baseline SBP/DBP values in grade 1 range and a low-to-moderate risk (<5% CV deaths in 10 y in controls): FEVER stratum with baseline SBP below the median (<153 mm Hg) (e7); HTN Detection and Follow-up Program stratum with baseline DBP 90–94 mm Hg and no CVD (e9); OSLO (e17); TOMHS (e28) and USPHS (e29). Risks of stroke, CHD, the composite of stroke and CHD, and all-cause death were significantly reduced by BP-lowering in these low-to-moderate risk pts (control group: average CV mortality 4.5% in10 y) with a moderate BP elevation (average SBP/DBP 145.5/91 mm Hg) at randomization. Standardized risk ratio associated with 10/5 reduction in BP: stroke 0.33 (95% CI: 0.11–0.98) CHD 0.68 (95% CI: 0.48–0.95) CVD death 0.57 (95% CI: 0.32–1.02) total death 0.53 (95% 0.35–0.80)

  - Compared outcomes of achieved on study SBP <130 vs. ≥130
  - Standardized Risk ratio associated with 10/5 reduction in BP: stroke 0.68 (95% CI: 0.57, 0.83) CHD 0.87 (95% CI: 0.76, 1.00) HF 0.92 (95% CI: 0.47, 1.77) CVD 0.81 (95% CI: 0.67, 1.00) CVD death 0.88 (95% CI: 0.77, 1.01) total death 0.88 (95% CI: 0.77, 0.99)

  - Outcomes of achieved on study SBP 130–139 vs. ≥140

appears safe, but only adds further reduction in stroke.
| Lonn EM, et al., 2016 (116) 27041480 | **Aim:** To assess efficacy of fixed-dose antihypertensive therapy in adults with intermediate CVD risk.  
**Study type:** Double-blind, placebo-controlled RCT, factorial design  
**Inclusion criteria:** Men ≥55 y and women ≥60 y at intermediate risk for CVD. No BP restrictions.  
**Exclusion criteria:**  
- Known CVD  
- Indications or contraindications to study meds  
- Mod/advanced CKD  
- Symptomatic hypotension  
**Intervention:** FDC of ARB (candesartan 16 mg/d) and diuretic (hydrochlorothiazide 12.5 mg/d) or placebo  
**Follow-up:** Median=5.6 y | **1° endpoint:** 1 co-1° CVD composite outcomes  
- CVD mortality, nonfatal MI, nonfatal stroke  
- Above plus cardiac arrest, HF, revascularization  
**Standardized Risk ratio associated with 10/5 reduction in BP:**  
- Stroke: 0.63 (95% CI: 0.52–0.77)  
- CHD: 0.77 (95% CI: 0.70–0.86)  
- HF: 0.76 (95% CI: 0.47–1.25)  
- CVD: 0.74 (95% CI: 0.62–0.88)  
- CVD death: 0.81 (95% CI: 0.67–0.97)  
- Total death: 0.87 (95% CI: 0.75–1.00)  
**Summary:**  
- Similar pattern of results for on-treatment DBP. |  
| Neaton JD et al., 1993 (117) 8336373 | **Aim:** To compare 6 antihypertensive drugs (representing different drug classes)  
**Study type:** Double-blind, placebo-controlled RCT  
**Inclusion criteria:**  
- Men and women 45–69 y  
- Not taking antihypertensive medications, with DBP 90–99 mm Hg  
- Taking 1 antihypertensive medication, with DBP <95 mm Hg and between 85–99 mm Hg after withdrawal of BP medications  
**Intervention:** Treatment (number):  
- Once daily (AM):  
  - Placebo (234)  
  - Chlorothalidone 15 mg/d (136)  
  - Amlodipine 5 mg/d (131)  
  - Enalapril 5 mg/d (135)  
  - Doxazosin 2 mg/d (134)  
  - Amlodipine 5 mg/d (131)  
  - Enalapril 5 mg/d (135) | **1° endpoint:** BP, QoL, side effects, chemistries, ECG, clinical events  
**Summary:**  
- Drugs (plus diet) more effective compared to placebo (plus diet) for control of BP.  
- Minimal differences between drug regimens |

<tr>
<td>Van Dieren S, et al., 2012 (118) 22677192</td>
<td>To assess differences in treatment effects of a fixed combination of perindopril–indapamide on major clinical outcomes in pts with type 2 DM across subgroups of CV risk.</td>
<td>DM-2, aged ≥55 y, with a history of major macrovascular or microvascular disease, or at least 1 other risk factor for vascular disease</td>
<td>Perindopril–indapamide or matching placebo</td>
<td>• The Framingham equation was used to calculate 5-y CVD risk and to divide participants into 2 risk groups, moderate-to-high risk (&lt;25% and no history of macrovascular disease), very high risk (&gt;25% and/or history of macrovascular disease). • Endpoints were macrovascular and microvascular events.</td>
<td>Relative effects of BP-lowering with perindopril–indapamide on CV outcomes were similar across risk groups whilst absolute effects trended to be greater in the high-risk group.</td>
</tr>
<tr>
<td>Montgomery AA, et al., 2003 (119) 12923409</td>
<td>To estimate the effectiveness and cost-effectiveness of BP-lowering treatment over a lifetime.</td>
<td>We created models for 20 different strata of sex, age (age 30–70 y in 10-y bands), and 2 risk profiles (designated as ‘low’ and ‘high’ risk). These example risk profiles represent the extremes of absolute CV risk, based on data from the Health Survey for England and using a Framingham risk function. We recognize that the risk of most individuals seen in primary care will be somewhere between the examples presented here. The data included were as follows: age- and sex-specific mean SBP of untreated individuals with SBP&gt;0.160 mm Hg were used for both high-risk and low-risk profiles. In addition, low-risk profile was defined as nonsmoker, 10th percentile total cholesterol 90th percentile HDL</td>
<td>Treatment and nontreatment of HTN.</td>
<td>Life expectancy, and incremental cost: effectiveness ratios for treatment and nontreatment strategies</td>
<td>Incremental cost per quality-adjusted life y among low-risk groups ranged from £1,030 to £3,304. Cost-effectiveness results for low-risk pts were sensitive to the utility of receiving antihypertensive treatment. Treatment of high-risk individuals was highly cost-effective, such that it was the dominant strategy in the oldest age group, and resulted in incremental costs per quality-adjusted life y ranging from £34–£265 in younger age groups. • Policy decisions about which pts to treat depend on whether a life-expectancy or cost-</td>

cholesterol, no DM, and no LVH, and high-risk profile was defined as smoker, 90th percentile total cholesterol, 10th percentile HDL cholesterol, DM, and LVH.

**Exclusion criteria:** N/A

Exclusion criteria: N/A

### Inclusion criteria: To estimate the rate of cv and non-CV deaths in a hypothetical U.S. population of untreated hypertensive pts, we used the following procedure: age-specific death rates in the U.S. general population were obtained from national vital statistics (1994), and in untreated hypertensive population they were obtained from the control groups of the INDANA database. This latter group represents a unique cohort of 14,942 untreated or placebo-treated hypertensive pts, 26–96 y with an average follow-up of 5 y

**Exclusion criteria:** N/A

### Intervention: The gain in life expectancy without stroke, CHD, and CV events was estimated from the area between the 2 survival curves of treated and control groups. The relative gain in life expectancy was defined as the ratio of gain in life expectancy to life expectancy.

### 1° endpoint: Stroke and CHD co-

a RR at 10 y
b Absolute benefit at 10 y
c NNT to avoid 1 event.
d Gain in life expectancy in mo without events.

**Summary:** Absolute gains in life expectancy are likely to be greater for younger, lower risk people with HTN than for older, higher risk people with HTN. However, the NNT to prevent an event will likely be greater especially in the short term in younger, lower risk people. This modeling analysis provides support for treating younger, lower risk individuals with HTN, but relies on the assumption that the relative benefits of treatments observed in short-term trials of higher risk individuals applies over a longer term to lower risk individuals.
survival curve of the life-long treated population. Gains in event-free life expectancy were estimated from survival curves. A sensitivity analysis was performed to assess the impact of possible death misclassifications.

**Size:** 6 RCTs, ~30,000 pts

---

Czernichow S et al., 2011 (121) 20881867

**Aim:** The objective of this systematic review and meta-analysis was to compare the relative reductions in risk achieved with different starting levels of BP (and treatment regimens).

**Study type:** Meta-analysis of RCTs

**Size:** 32 trials with 201,566 pts (20,079 1° outcome events)

**Inclusion criteria:** RCTs of BP-lowering (drug vs. control or less intensive treatment) or different classes of drug therapy that included a minimum of 1,000 pt-y of follow-up in each study arm.

**Exclusion criteria:** <1,000 pt-y of follow-up in each treatment group.

**Intervention:** BP-lowering meds

**Comparator:** Placebo, active comparator or less intensive treatment

**1° endpoint:**
- Major CVD events (stroke, CHD, and HF).
- No evidence of differences in the ratio of risk across varying levels of baseline BP (with all classes of BP-lowering medications).

**Summary:**
- Effectiveness of BP-lowering regimens in reducing RR of major CVD events does not seem to be influenced by starting level of BP.

**Limitations:**
- The majority of the participants studied were at high risk for CVD.
- Information pertaining to the effect of treatment on absolute risk was not presented in this manuscript.

| **VA NEPHRON-D** Fried LF, et al., 2013 (124) 24206457 | **Aim:** Assess the efficacy of combination of an ACEI and an ARB vs. ARB monotherapy in reducing the progression of proteinuric diabetic nephropathy  **Study type:** Multicenter, double-blind, RCT at 32 VA Medical Centers  **Size:** 1448 pts | **Inclusion criteria:** Pts with type 2 DM, a urinary albumin-to-creatinine ratio of ≥300, and an eGFR 30.0–89.9 mL/min/1.73 m²  **Exclusion criteria:**  
- Subjects with known non diabetic kidney disease  
- Serum K+ >5.5 mmol/L  
- Current treatment with sodium polystyrene sulfonate  
- Inability to stop prescribed medication that increases the risk of hyperkalemia  | **Intervention:** Losartan 100 mg daily plus lisinopril 10–40 mg daily (n=724)  **Comparator:** Losartan 100 mg daily plus placebo (n=724) | **1° endpoint:** After a median follow-up of 2.2 y, the study was stopped early due to safety concerns. There was no difference in the 1° outcome of first occurrence of change in eGFR (decrease of ≥30 mL/min/1.73 m² if initial GFR was ≥60 mL/min/1.73 m² or a decline of ≥50% if initial eGFR was <60 mL/min/1.73 m²), ESRD, or death (HR with combination therapy: 0.88; 95% CI: 0.70–1.12; p=0.30).  | **Safety endpoint:** Combination therapy increased the risk of hyperkalemia (HR: 2.8; 95% CI: 1.8–4.2; p<0.001) and acute kidney injury (HR: 1.7; 95% CI: 1.3–2.2; p<0.001).  |
| **ALTITUDE** Parving HH, et al., 2012 (125) 23121378 | **Aim:** Determine if addition of aliskiren as an adjunct to an ACEI or ARB reduces the risk of CV and renal events in pts with type 2 DM | **Inclusion criteria:** ≥35 y with type 2 DM  
- On ACEI or ARB  
- At least 1 of the following: persistent macroalbuminuria (urine microalbumin to creatinine ratio ≥200 mg/g) and eGFR ≥30 mL/min/1.73 m², persistent macroalbuminuria (≥20 mg/g and <200 mg/g) and a mean eGFR ≥30 and <60  | **Intervention:** Aliskiren 300 mg daily added to conventional treatment with an ACEI or ARB (n=4,274)  **Comparator:** Placebo (n=4,287) | **1° endpoint:** After a median follow-up of 32.9 mo the study was stopped early. There was no difference in the 1° composite outcome death from CV causes or first occurrence of cardiac arrest with resuscitation, which was increased significantly with aliskiren (HR: 2.40; 95% CI: 1.05–5.48; p=0.04).  | **2° endpoint:** There was no difference in the 2° endpoint of first occurrence of change in eGFR or ESRD (HR: 0.78; 95% CI: 0.58–1.05; p=0.10). There were no differences between combination therapy or losartan monotherapy for the endpoints of ESRD, death, composite of MI, HF, or stroke, MI, CHF, and stroke (p>0.05 for all).  |

© 2017 American College of Cardiology Foundation and American Heart Association, Inc.
Study type: Doubled-blind, multicenter RCT

Size: 8561

Inclusion criteria:
- mL/min/1.73 m², or history of CVD (e.g., MI, stroke, HF, or CAD) and a mean eGFR ≥30 and <60 mL/min/1.73 m²

Exclusion criteria:
- Serum K+ >5.0 mmol/L
- Type 1 DM
- Unstable serum Cr
- CV history (NYHA Class III or IV, SBP ≥170 mm Hg or DBP ≥110 mm Hg or SBP ≥135 and <170 mm Hg or DBP ≥82 and <100 mm Hg with at least 3 agents, 2nd or third degree heart block, renal artery stenosis
- Surgical or medical conditions (malignancy in last 5 y, <2 y life expectancy, renal transplant or immunosuppressive therapy, drug/alcohol abuse, hypersensitivity/allergy/contraindication to study drugs, pregnancy)
- Concomitant treatment with ≥2 agents blocking RAAS or K+-sparing diuretics.

Intervention: Ramipril 10 mg daily (n=8,576)

Comparator:
- Telmisartan 80 mg daily (n=8,542)
- Combination of telmisartan and ramipril (n=8,502)

1° endpoint: After a median follow-up of 56 mo, there was no difference between ramipril vs. telmisartan or combination therapy vs. ramipril in the 1° composite outcome of death from CV causes, MI, stroke, or hospitalization for HF (RR: 1.01; 95% CI: 0.94–1.09 and RR: 0.99; 95% CI: 0.92–1.07, respectively)

Safety endpoint:
- Combination therapy was associated with greater risk of hyperkalemia than

ONTARGET

Yusuf S, et al., 2008 (126) 18378520

Aim: Evaluate whether use of an ARB was noninferior to ACEI, and whether the combination was superior to ACE alone in the prevention of vascular events in pts with CVD or DM but not HF.

Study type: Multi-center, double-blind, RCT

Inclusion criteria:
- ≥55 y
- Coronary, peripheral, or cerebrovascular disease or DM with end-organ damage

Exclusion criteria:
- Inability to discontinue ACEI or ARB
- Known hypersensitivity or intolerance to ACEI or ARB
- Selected CVDs (congestive HF, hemodynamically significant valvular or outflow tract obstruction, constrictive pericarditis, complex congenital heart disease, syncopal episodes of unknown etiology <3 mo, planned cardiac surgery

Intervention: Ramipril 10 mg daily (n=8,576)

Comparator:
- Telmisartan 80 mg daily (n=8,542)
- Combination of telmisartan and ramipril (n=8,502)

1° endpoint: After a median follow-up of 56 mo, there was no difference between ramipril vs. telmisartan or combination therapy vs. ramipril in the 1° composite outcome of death from CV causes, MI, stroke, or hospitalization for HF (RR: 1.01; 95% CI: 0.94–1.09 and RR: 0.99; 95% CI: 0.92–1.07, respectively)

Safety endpoint:
- Combination therapy was associated with greater risk of hyperkalemia than

2° endpoint:
- There was no difference in composite of death from CV causes, MI, or stroke in the ramipril vs. telmisartan groups RR: 0.99; 95% CI: 0.9–1.07); p=0.001 or ramipril vs. combination RR: 1.00; 95% CI: 0.93–1.09
- There were no differences between ramipril vs. telmisartan or ramipril vs. combination therapy in 2° outcomes including MI, stroke, hospitalization for HF, death from CV causes, death from non-CV causes, or death from any cause (p>0.05 for all).

© 2017 American College of Cardiology Foundation and American Heart Association, Inc. 84
or PTCA <3 mo, uncontrolled HTN on treatment [e.g., BP >160/100 mm Hg], heart transplant recipient, stroke due to subarachnoid hemorrhage

- Other conditions (significant renal artery disease, hepatic dysfunction, uncorrected volume or sodium depletion, 1° hyperaldosteronism, hereditary fructose intolerance, other major noncardiac illness or expected to reduce life expectancy or significant disability interfere with study participation, simultaneously taking another experimental drug, unable to provide written informed consent).

ramipril monotherapy (480 pts vs. 283 pts; p<0.001)

- Hypotensive symptoms were cited as reason for permanent discontinuing more in telmisartan vs. ramipril (RR: 1.54; p<0.001) and combination therapy vs. ramipril monotherapy (RR: 2.75; p<0.001)

- Renal impairment was more common in combination therapy vs. ramipril monotherapy RR: 1.33; 95% CI: 1.2–1.44

Summary: Combination therapy with telmisartan and ramipril did not decrease the risk of CV events in pts at high risk compared to monotherapy with ramipril. In addition, combination therapy was associated with increased risk of hypotension, hyperkalemia, and renal impairment.

**Study type:**
- **Cumulative meta-analysis of RCTs to study benefit of more vs. less intensive BP lowering**
- **Network meta-analysis in which the authors attempted to compare the benefits and adverse effects resulting from intensive reduction in SBP**

**Size:**
- 18 trials (n=53,405)
- 17 trials (n=55,163)

**Outcome Measures:**
- Stroke, MI, HF, CVD mortality, and all-cause mortality
- Difference in achieved SBP/DBP=7.6/4.5 mm Hg
- For stroke and MI the cumulative Z score crossed the efficacy boundary after addition of the SPRINT results
- For CVD mortality and HF, the cumulative Z curve crossed the conventional significance boundary (but not the sequential monitoring boundary)
- For all-cause mortality, the cumulative Z curve did not reside in the futility area but did not cross the conventional significance boundary
- The results strongly supported the benefit of intensive BP reduction for prevention of stroke and MI and suggested benefit for prevention of CVD mortality and HF
- There was a significant reduction in stroke (RR: 0.54) and MI (RR: 0.68)
- The point estimate favored all-cause mortality, CVD mortality and HF but the results did not achieve significance
- SBP targets <120 and <130 mm Hg ranked #1 and #2 as the most efficacious
- Serious adverse effects were more common at a lower SBP (120 vs. 150 or 140 mm Hg)
- Overall, the beneficial effects of treatment were consistent with other reports. The cluster plots of treatment benefit vs. risk are difficult to interpret due to limitations of the available database and the authors’ decision to weight treatment benefits and potential adverse effects equally.
| Bundy JD, et al., 2017 | Study type: Systematic review and network meta-analysis to assess the benefits of intensive SBP reduction during treatment of hypertension | N/A | N/A | • Cluster plots for combined efficacy and safety suggested a SBP <130 mm Hg as the optimal target for SBP reduction during treatment |

| Bundy JD, et al., 2017 | **Study type**: Systematic review and network meta-analysis to assess the benefits of intensive SBP reduction during treatment of hypertension  
**Size**: 42 trials (n=144,220) | N/A | N/A | • In general, there were linear associations between achieved SBP and risk of CVD and all-cause mortality, with the lowest risk at a SBP of 120–124 mm Hg. |

| Lawes CMM, et al., 2002 | Study type: Review of observational reports and randomized controlled trials | N/A | N/A | • This was by far the largest and best powered meta-analysis to assess the relationship between SBP reduction and major outcomes during treatment of hypertension. The findings provided strong evidence for the “lower is better” approach to treatment in patients with a high SBP who are at high risk for CVD. |

| Lawes CMM, et al., 2002 | **Study type**: Review of observational reports and randomized controlled trials | N/A | N/A | • The relative benefits of BP lowering for CHD prevention likely to be consistent across a wide range of different populations  
• Likely to be considerable benefit for BP lowering beyond traditional thresholds, especially in those at high risk for CVD  
• BP lowering is likely to be more important than choice of initial agent  
• A large majority of patients being treated for... |

| Lawes CMM, et al., 2002 | **Study type**: Review of observational reports and randomized controlled trials | N/A | N/A | • Strongly supports lower BPs during BP treatment, especially in those at high risk of CVD |
hypertension have suboptimal BPs. Initiatives to lower their BP further are essential.

- HF RR: 0.85 (95% CI: 0.66–1.11)
- CVD death RR: 0.91 (95% CI: 0.74–1.11)
- Total deaths RR: 0.91 (95% CI: 0.81–1.03)

### Other results:
- Benefit for CVD not different by baseline SBP
  - 120–139: 0.89 (95% CI: 0.76–1.05)
  - 140–160: 0.83 (95% CI: 0.68–1.00)
  - >160: 0.89 (95% CI: 0.73–1.09)
  - *p*-heterogeneity: 0.60
- Benefit for CVD not different for more intensive and less intensive targets in intensive group
  - <140 or <150 mm Hg: 0.76 (95% CI: 0.60–0.97)
  - <120–<130 mm Hg: 0.91 (95% CI: 0.84–1.00; *p*-hetero: 0.06)
- Absolute benefits were proportional to absolute risk.
- For trials in which all pts had vascular disease, renal disease, or DM at baseline, the average control group rate of major vascular events was 2.9% per y compared with 0.9% per y in other trials, and the numbers needed to treat were 94 (95% CI: 77–115) for trials with and without CVD at threshold of <130 mm Hg.

### Neaton JD, et al., 1993 (117) 8336373

**Aim:** To compare 6 antihypertensive drugs (representing different drug classes)  
**Study type:** Double-blind, placebo-controlled RCT  
**Size:** 902 pts with stage 1 HTN  

**Inclusion criteria:**  
- Men and women 45–69 y  
- Not taking antihypertensive medications, with DBP 90–99 mm Hg  
- Taking 1 antihypertensive medication, with DBP <95 mm Hg and between 85–99 mm Hg after withdrawal of BP medications

**Intervention:**  
- Treatment (number):  
  - Placebo (234)  
  - Chlorthalidone 15 mg/d (136)  
  - Acebutolol 400 mg/d (132)  
  - Doxazosin 2 mg/d (134)  
  - Amlodipine 5 mg/d (131)  
  - Enalapril 5 mg/d (135)  

**Follow-up:** Median=4.4 y  

**1° endpoint:** BP, QoL, side effects, chemistries, ECG, clinical events  

**Summary:**  
- Drugs (plus diet) more effective compared to placebo (plus diet) for control of BP.  
- Minimal differences between drug regimens

| Psaty BM, et al., 2003 12759325     | Study type: Network meta-analysis to compare value of different first-line antihypertensive drugs in prevention of major CVD and all-cause mortality  
Size: 42 trials (n=192,478) | N/A | For all outcomes, low-dose diuretics were better than placebo  
- None of the other first-line agents (β-blockers, ACEI, CCBs, α-receptor blockers and ARBs) were superior to low-dose diuretics  
- For several outcomes, low-dose diuretics were superior to other agents | Low-dose diuretics were identified as the most effective first-line treatment for prevention of CVD and all-cause mortality during treatment of hypertension | N/A |
| Brunström M, et al., 2016 (53) | **Study type:** Meta-analysis of levels of BP control in DM hypertensives.  
**Size:** 73,738 pts | **Baseline SBP >150**  
**RR for**  
- All death: 0.89; 95% CI:0.80–0.99  
- CVD: 0.75; 95% CI: 0.57–0.99  
- MI: 0.74; 95% CI: 0.63–0.87  
- Stroke: 0.77; 95% CI: 0.65–0.91  
- ESRD: 0.82; 95% CI: 0.71–0.94  
Baseline SBP140–150 RR of  
- Death: 0.87; 95% CI: 0.78–0.98  
- MI: 0.84; 95% CI: 0.76–0.9  
- HF: 0.80; 95% CI: 0.66–0.97  
If baseline SBP,140 mm Hg, however, further treatment increased the risk of CV mortality (1.15; 95% CI: 1.00–1.32)  
- BP lowering reduces major CV events in DM. Caution for initiating treatment in diabetics with SBP <140/90 | N/A |
| Ettehad D, et al., 2015 (17) | **Study type:** Meta-analysis of large RTCs of antihypertensive treatment  
**Size:** 123 studies (613,815 pts) | Every 10 mm Hg reduction in SBP RR:  
- Major CV events: 0.80; 95% CI: 0.77–0.83  
- CHD: 0.83; 95% CI: 0.78–0.88  
- Stroke: 0.73; 95% CI: 0.68–0.77, HF (0.72, 0.67–0.78  
- All-cause mortality: 0.87; 95% CI: 0.87; 0.84–0.91  
- ESRD: 0.95; 0.84–1.07  
- BP lowering reduces CV risk across various baseline BP levels and comorbidities. Suggest lowering SBP <130 mm Hg and BP-lowering treatment to pts with a history of CVD, CHD, stroke, DM, HF, and CKD. | N/A |
| Thomopolous C, et al., 2016 (54) | **Study type:** Meta-analysis of RTCs of more vs. less intense BP control  
**Size:** 16 trials (52,235 pts) compared more vs. less intense treatment  
34 (138,127 pts) active vs. placebo | More intense BP  
- Stroke RR: 0.71; 95% CI: 0.60–0.84)  
- CHD RR: 0.80; 95% CI: 0.68–0.95  
- Intensive BP reduction improves CV outcomes compared to less intense  
- Achieved BP <130/80 may be associated with CV benefit. | N/A |
### 2017 Hypertension Guideline Data Supplements

| Study Reference | Study type | Study Details | Major CV events RR: 0.75; 95% CI: 0.68–0.85  | CV mortality RR: 0.79; 95% CI: 0.63–0.97  
| Stratification of SBP cutoffs (150,140 and 130 mm Hg) showed that a SBP/DBP difference of 10/5 mm Hg across each cutoff reduced risk of all outcomes |  |
| --- | --- | --- | --- | --- |
| Julius S, et al., 2006 (55) 16537662 | Study type: RCT in pre-HTN 16 mg candesartan vs. placebo  
Size: 809 pts | 58% men | - During the first 2 y, HTN developed in 154 (40.4%) pts in the placebo group compared with only 53 (13.6%) of those in the candesartan group, for a RR of 66.3% (p<0.0001). After 4 y, HTN developed in 240 (63.0%) in the placebo group vs. only 208 (53.2%) in the candesartan group RR 15.6% (p<0.0069).  
- 2/3 of those with pre-HTN develop HTN within 4 y. Candesartan interrupts the onset and reduced by 15.6% | N/A |
| Ference BA, et al., 2014 (56) 24591335 | Study type: Evaluated the effect of 12 polymorphisms (associated with BP) on the odds of CHD and compared it with the effect of lower SBP observed in both prospective cohort studies and BP-lowering randomized trials  
Size: 199,477 pts in 63 studies | N/A | - 12 polymorphisms were associated with a 0.32 mm Hg lower SBP (p=1.79×10⁻⁷) and a 0.093-mm Hg/decade slower age-related rise in SBP (p=3.05×10⁻⁴). The effect of long-term exposure to lower SBP on CHD mediated by these polymorphisms was 2-fold greater than that observed in prospective cohort studies (p=0.006) and 3-fold greater than that observed in short-term BP treatment trials (p=0.001).  
- SBP may be causally associated with the rate of rise in SBP with age and has a cumulative effect on the risk of CHD. | N/A |

| Ambrosius WT, et al., 2014 (122) 24902920 | **Aim:** To describe the study design of the SPRINT trial  
**Study type:** description of study design and protocol for the SPRINT RCT | **Inclusion criteria:**  
Adults ≥50 y, average SBP ≥130 mm Hg and evidence of CVD, CKD, or 10-y Framingham risk score ≥15%, or age ≥75 y | **Intervention:** 9361 participants randomized to 2 treatment groups: (1) Standard treatment group, SBP target <140 mm Hg, and (2) Intensive treatment group: SBP target <120 mm Hg. | **1° endpoint:** MI, ACS, stroke, HF, or CVD death. | Relevant 2° endpoint: All-cause mortality, decline in kidney function or development of ESRD, incident dementia, decline in cognitive function, and small-vessel cerebral ischemic disease  
Summary: This paper describes the protocol followed in the SPRINT trial that was successful in helping participants to attain and maintain BP targets in the study groups. Once treated, participants had follow-up visits to assessment BP control monthly until BP was at target. Medications were titrated and added as per protocol, when target BP was not attained. |
| Cushman WC, et al., 2007 (123) 17599425 | **Aim:** To describe the study design of the BP trial of the ACCORD trial.  
**Study type:** description of study design and protocol | **Inclusion criteria:**  
Adults with a diagnosis of type 2 DM for at least 3 mo and at high risk for CVD events, who meet the following BP criteria: (1) SBP 130–160 mm Hg and taking 0–3 antihypertensive medications; (2) SBP 161–170 and on 0–2 antihypertensive | **Intervention:**  
- Unmasked, open-label, factorial design, randomized trial with a sample size of 4,733 pts  
- Patients were randomized to intensive SBP control (<120 mm Hg) or standard control (<140 mm Hg) | **1° endpoint:** Major CVD event (nonfatal MI or stroke, or CV death) | **Relevant 2° endpoint:** Expanded macrovascular outcome (1° outcome plus coronary revascularization or HF hospitalization), total mortality, each of the separate components of the 1° outcome, HF death or hospitalization, and... |
for the ACCORD RCT medications; or (3) SBP 171–180 and taking 0–1 antihypertensive medication. Other entry criteria included spot urine sample <2+, protein–Cr ratio <700 mg protein/1 g creatinine, or 24-h protein excretion <1.0 g/24 h. composite microvascular disease outcome (kidney and eye disease).

**Summary:** This paper describes the protocol followed in the ACCORD trial that was successful in helping pts to attain and maintain BP targets in the study groups. Once treated, pts had follow-up visits to assessment BP control monthly until BP was at target. Medications were titrated and added as per protocol, when target BP was not attained.

<td><strong>Aim</strong>: Assess impact of follow-up and monitoring system including home BP monitoring and telephonic nurse case management on BP control in pts treated for HTN  <strong>Study type</strong>: RCT  <strong>Size</strong>: 638 African American pts with high BP from a national health maintenance organization plan</td>
</tr>
</tbody>
</table>
| Bosworth, et al., 2009 (131) | **Aim:** Assess impact of telephone follow-up intervention and/or home BP monitoring on BP control in pts with treated HTN  
**Study type:** RCT  
**Size:** 636 pts were randomized; 475 pts completed the trial, including 24-mo follow-up period. | **Inclusion criteria:** Pts with HTN, from 2 university-affiliated primary care clinics.  
- 636 pts randomized to usual care or 1 of 3 intervention groups: (1) Nurse-administered telephone intervention targeting HTN-related behaviors, (2) home BP monitoring 3 times weekly, and (3) both interventions  
- 475 pts (75%) completed the 24-mo BP follow-up.  
- At 24 mo, improvements in the proportion of pts with BP control relative to the usual care group were 4.3% (95% CI: -4.5%, 12.9%) in the behavioral intervention group, 7.6% (95% CI: -1.9%, 17.0%) in the home BP monitoring group, and 11.0% (95% CI: 1.9%, 19.8%) in the combined intervention group.  
- Relative to usual care, the 24-mo difference in SBP was 0.6 mm Hg (95% CI: -2.2, 3.4 mm Hg) for the behavioral intervention group, -0.6 mm Hg (95% CI: -3.6, 2.3 mm Hg) for the BP monitoring group, and -3.9 mm Hg (95% CI: -6.9 to -0.9 mm Hg) for the combined intervention group; patterns were similar for DBP.  
- Home BP monitoring and tailored behavioral telephone intervention improved BP control, SBP, and DBP at 24 mo relative to usual care. Combined therapy was significantly better than either therapy alone. |  |
| Bosworth, et al., 2011 (132) | **Aim:** Assess impact of telephone follow-up interventions on BP control in pts with treated HTN  
**Study type:** RCT  
**Size:** Of 1551 eligible pts, 593 randomized | **Inclusion criteria:** Primary care clinics at a VA Medical Center  
- 593 pts randomized to either usual care or to 1 of 3 telephone follow-up groups: (1) nurse-administered behavioral management, (2) nurse- and physician-administered medication management, or (3) a combination of both  
- 1° endpoint: BP control measured every 6 mo for 18 mo  
- Behavioral management and medication management alone showed significant improvements at 12 mo-12.8% (95% CI: 1.6%, 24.1%) and 12.5% (95% CI: 1.3%, 23.6%), respectively—but not at 18 mo.  
- In subgroup analyses, among those with poor baseline BP control, SBP decreased in the combined intervention group by 14.8 mm Hg (95% CI: -21.8 to -7.8 mm Hg) at 12 mo and 8.0 mm Hg (95% CI: -15.5 to -0.5 mm Hg) at 18 mo, relative to usual care.  
- Telephone-based case management for high BP control effectively lowers BP for up to 1 y, but then BP control slackens.  
- Interventions had the most impact on pts with worst BP control at study entry.  
- Study carried out in the Veteran’s Administration outpatient practice; unclear if results would apply to other practice settings. |  |

## Summary

The optimal SBP in pts ≥60 y with CAD and SBP >150 mm Hg treated with antihypertensive therapy was <140 mm Hg.

### Law MR, et al., 2009 (18) 19454737

**Study type:** Meta-analysis of use of BP-lowering drugs in prevention of CVD from 147 randomized trials

**Size:** Of 147 randomized trials of 464,000 pts, 37 trials of BBs in CAD included 38,892 pts, and 37 trials of other antihypertensive drugs in CAD included 85,395 pts

**Inclusion criteria:** The database search used Medline (1966 to Dec. 2007) to identify randomized trials of BP-lowering drugs in which CAD events or strokes were recorded. The search also included the Cochrane Collaboration and Web of Science databases and the citations in trials and previous meta-analyses and review articles.

**Exclusion criteria:** Trials were excluded if there were <5 CAD events and strokes or if treatment duration was <6 mo.

**1° endpoint:** CAD events; stroke

**Results:** In 37 trials of pts with a history of CAD, BBs reduced CAD events 29% (95% CI: 22%, 34%). In 27 trials in which BBs were used after acute MI, BBs reduced CAD events 31% (95% CI: 24%–38%), and in 11 trials in which BBs were used after long-term CAD, BBs insignificantly reduced CAD events 13%. In 7 trials, BBs reduced stroke 17% (95% CI: 1%–30%). CAD events were reduced 14% (95% CI: 2%–25%) in 11 trials of thiazide diuretics, 17% (95% CI: 11%–22%) in 21 trials of ACEIs, insignificantly 14% in 4 trials of angiotensin receptor blockers, and 15% (95% CI: 8%–22%) in 22 trials of CCBs. Stroke was reduced 38% (95% CI: 20%–47%) in 10 trials of thiazide diuretics, 22% (95% CI: 8%–34%) in 13 trials of ACEIs, and 34%

- With the exception of the extra protective effect of BBs given shortly after a MI and the minor additional effect of CCBs in preventing stroke, all the classes of BP-lowering drugs have a similar effect in reducing CAD events and stroke for a given reduction in BP.

**The Multicenter Diltiazem Postinfarction Research Group 1988 (145)**

**Aim:** To assess diltiazem effect on recurrent infarction and death after acute MI

**Study type:** RCT

**Size:** 2,466 pts

**Inclusion criteria:** 25–75 y admitted to CCU, MI with enzyme confirmation.

**Exclusion criteria:**
- Cardiogenic shock,
- Symptomatic hypotension,
- PH with right HF,
- 2nd/3rd degree heart block,
- HR <50 bpm,
- Contraceptives,
- WPW syndrome,
- CCBs,
- Severe comorbidities or
- Cardiac surgery

**Intervention:** Diltiazem 240 mg (1,234)

**Comparator:** Placebo (1,232)

**1° endpoints and results:**
- Total mortality: identical in both groups
- Cardiac death and nonfatal MI: 11% fewer in diltiazem but difference was NS

**Follow-up Results:** Pts with BL EF<0.40, late CHF in Diltizam group (21%) vs. Placebo (12%) [p=0.004].

- No combined benefit from diltiazem on mortality or cardiac events

**MDPIT**

**Goldstein RE, et al., 1991 (146)**

**Aim:** To determine if diltiazem increases late onset CHF in post-MI pts with early decline in EF.

**Study type:** RCT

**Size:** 2,466 pts

**Inclusion criteria:** Same as above

**Exclusion criteria:** Same as above

**Intervention:** Diltiazem 240 mg (1,234)

**Comparator:** Placebo (1,232)

**1° endpoint and results:** Same as above

**Follow-up Results:**
- Life table analysis confirmed increased frequency of late CHF in pts taking diltiazem (p=0.0017)
- Diltiazem related CHF exclusively associated with systolic LVD with or without BBs

### Studies

#### Study type: RCT (triple crossover)

**Size:** 11 pts

**Exclusion criteria:** LVD with CHF or LVEF <30% at rest and <25% for exercise, HR <50 b/min, ≥first degree heart block

**Comparator:** Placebo

**Aim:** To determine if active treatment reduces complications from isolated systolic HTN in the elderly.

**Inclusion criteria:** Pts ≥60 y, sitting SPB 160–219 mm Hg, sitting DBP 95 mm Hg, and standing SBP ≥140 mm Hg.

**Intervention:** Active treatment (2,398)

**Comparator:** Placebo (2,297)

**1° endpoint:** Fatal and nonfatal strokes combined.

**Results:** 13.7 vs. 7.9 endpoints/1,000 pts-y (42% reduction; p=0.003)

- All fatal and nonfatal cardiac endpoints (with sudden death) decreased in the active treatment group (p=0.03)
- Cardiac mortality was lower in active treatment (-27%; p=0.07). All-cause mortality was not different.
- Nitrendipine used for active arm.

#### Study type: RCT

**Size:** 4,965 pts

**Exclusion criteria:** Systolic HTN 2nd to a disorder, retinal hemorrhages/papilledema, CHF, aneurysms, serum Cr ≥180 µmol/L, history of nosebleed, stroke, MI <1 y, dementia, substance abuse, severe comorbidities

**Intervention:** 4,678 pts were randomized to intensive BP treatment

**Comparator:** 4,683 pts were randomized to standard BP treatment

**1° endpoint:** At 1 y, the mean SBP was 121.4 mm Hg with intensive treatment (mean number of antihypertensive drugs was 2.8) and 136.2 mm Hg with standard treatment (mean number of antihypertensive drugs was 1.8)

- At 3.26-y median follow-up, compared with standard BP treatment, intensive BP treatment reduced all-cause mortality 27% (p=0.003), HF 38% (p=0.002), CV mortality 43% (p=0.005), and the 1° composite outcome or death 22% (p<0.001)
- Intensive BP treatment reduced the 1° composite endpoint 33% (14% to 49%) in pts aged 75 y and older and 20% (0% to 36%) in pts 50–74 y
- Serious adverse events were similar in both treatment groups. However, intensive BP treatment caused more hypotension (2.4% vs. 1.4%; p=0.001), more syncope (2.3% vs. 1.7%; p=0.05), more

</tbody>
</table>
| **Aim:** In a follow-up analysis, to compare diuretic vs. alpha-blocker as first step treatment of hypertension.  
**Inclusion criteria:** Men and women ≥ 55 y with BP ≥140/90 mm Hg or on medications for hypertension with at least one additional risk factor for coronary heart disease.  
**Intervention:** 15,255 patients were randomized to chlorthalidone and 9,061 to doxazosin and followed for 3.2 y.  
**Primary endpoint:** Combined fatal coronary heart disease or non-fatal MI, analyzed by intention to treat.  
- There was no difference in primary outcome between the arms (RR: 1.02; 95% CI: 0.94–1.13).  
- However, the doxazosin arm compared with the chlorthalidone arm had a higher risk for stroke (RR: 1.26; 95% CI: 1.10–1.46) and combined cardiovascular disease (RR: 1.20; 95% CI: 1.13–1.27).  
- The findings confirmed the superiority of diuretic-based over alpha blocker based antihypertensive treatment in the prevention of cardiovascular disease. |

| **Zanchetti A, et al., 2006 17053536** |
| **Aim:** To provide additional analyses of the primary endpoint in the VALUE trial, including sex, age, race, geographic region, smoking status, type 2 diabetes, total cholesterol, left ventricular hypertrophy, proteinuria, serum creatinine, history of coronary heart disease, stroke or transient ischemic attack and history of peripheral artery disease.  
**Inclusion criteria:** The 15,245 patients participating in VALUE were divided into subgroups according to baseline characteristics.  
**Statistical analysis:** Subgroup interaction analyses were conducted by the Cox proportion hazard model. Within each subgroup, treatment effects were assessed by hazard ratios and 95% CIs.  
- For cardiac morbidity and mortality, the only significant subgroup by treatment interaction was of sex (p=0.016) with HR indicating a relative excess of cardiac events in women but not in men, but SBP differences in favor of amlodipine were greater in women.  
- In the VALUE cohort, in no subgroup of patients were there differences in the incidence of the composite cardiac endpoint with valsartan and amlodipine treatment despite greater BP reduction in the amlodipine group. |
Leenen FHH, et al., 2006

Aim: To compare the long-term relative safety and outcomes of ACE inhibitor- and CCB-based regimens in older hypertensive individuals in ALLHAT.

Inclusion criteria: men and women age ≥55 y with untreated (BP 140–180/90–110 mm Hg) or treated hypertension (BP ≤160/100 mm Hg on ≤2 antihypertensive drugs) with ≥ 1 additional risk factor for coronary heart disease.

Intervention: Patients (were randomized to amlodipine (9,048) or Lisinopril (9,054).

Primary outcome: Combined fatal coronary heart disease or non-fatal MI, analyzed by intention to treat.

Follow-up: 4.9 y

• Risk of coronary heart disease was similar between amlodipine and Lisinopril
• For stroke, combined cardiovascular disease, gastrointestinal bleeding and angioedema, risks are higher with Lisinopril compared to amlodipine.
• For heart failure, risks are higher with amlodipine compared to Lisinopril.

Data Supplement 31. Meta-analyses of ischemic heart disease (Section 9.1)

| Bundy JD, et al., 2017 28564682       | Study type: Network meta-analysis | **Inclusion criteria:**  
  • Random allocation into an antihypertensive medication, control or treatment target  
  • Allocation to antihypertensive Antihypertensive treatment was independent of other treatment regimen  
  • ≥100 patients in each treatment group  
  • Trial duration ≥ 6 mo  
  • One or more events for each treatment group reported  
  • Minimum 5 mm Hg difference in SBP level between the 2 treatment groups  
  • Outcomes included major CVD, stroke, CHD, CVD mortality or all-cause mortality | **Primary Endpoint and Results:**  
  • There were linear associations between mean achieved SBP and risk of cardiovascular disease and mortality, with the lowest risk at 120 to 124 mm Hg. Randomized groups with a mean achieved SBP of 120 to 124 mm Hg had a hazard ratio (HR) for major cardiovascular disease of 0.71 (95% CI: 0.60–0.83) compared with randomized groups with a mean achieved SBP of 130 to 134 mm Hg, an HR of 0.58 (95% CI: 0.48–0.72) compared with those with a mean achieved SBP of 140 to 144 mm Hg, an HR of 0.46 (95% CI: 0.34–0.63) compared with those with a mean achieved SBP of 150 to 154 mm Hg, and an HR of 0.36 (95% CI: 0.26–0.51) compared with those with a mean achieved SBP of 160 mm Hg or more. | **Summary/Conclusion Comment(s):**  
  • This study suggests that reducing SBP to levels below currently recommended targets significantly reduces the risk of cardiovascular disease and all-cause mortality and strongly support more intensive control of SBP among adults with hypertension. |
Data Supplement 32. Nonrandomized Trials, Observational Studies, and/or Registries of Ischemic Heart Disease (Section 9.1)

<tr>
<td>PROVE IT-TIMI 22 Bangalore S, et al., 2010 (151) 21060068</td>
<td><strong>Study type:</strong> Nonrandomized trial of optimal BP after ACS  <strong>Size:</strong> 4,162 pts</td>
<td><strong>Inclusion criteria:</strong> Pts with acute MI or high-risk UA within 10 d randomized to pravastatin or atorvastatin and to gatifloxacin or placebo treated with standard medical and interventional treatment for ACS  <strong>Exclusion criteria:</strong> N/A</td>
<td><strong>1° endpoint:</strong> Composite of all-cause death, MI, UA requiring rehospitalization, revascularization after 30 d, and stroke with a mean follow-up of 24 mo  <strong>Results:</strong> The relationship between SBP and DBP followed a J- or U-shaped curve association with the 1° outcome with increased events rates at both low and high BP values. A nonlinear Cox proportional hazards model showed a nadir of 136/85 mm Hg (range 130–140/80–90 mm Hg) at which the incidence of 1° outcome was lowest. There was a relatively flat curve for SBP of 110–130 mm Hg and for DBP of 70–90 mm Hg, suggesting a BP &lt;110/70 mm Hg may be dangerous.</td>
<td>• After an ACS, a J- or U-shaped association existed between BP and the incidence of new CV events. The lowest incidence of CV events occurred with a BP of 130–140/80–90 mm Hg and a relatively flat curve for SBP of 110–130 mm Hg and of DBP of 70–90 mm Hg, suggesting a BP &lt;110/70 mm Hg may be dangerous.</td>
</tr>
<tr>
<td>Law MR, et al., 2009 (18) 19454737</td>
<td><strong>Study type:</strong> Meta-analysis of use of BP-lowering drugs in prevention of CVD from 147 randomized trials  <strong>Size:</strong> Of 147 randomized trials of 464,000 pts, 37 trials of BBs in CAD included 38,892 pts, and 37 trials of other antihypertensive drugs in CAD included 85,395 pts</td>
<td><strong>Inclusion criteria:</strong> The database search used Medline (1966 to Dec. 2007) to identify randomized trials of BP-lowering drugs in which CAD events or strokes were recorded. The search also included the Cochrane Collaboration and Web of Science databases and the citations in trials and previous meta-analyses and review articles.  <strong>Exclusion criteria:</strong> Trials were excluded if there were &lt;5 CAD events and strokes or if treatment duration was &lt;6 mo.</td>
<td><strong>1° endpoint:</strong> CAD events; stroke  <strong>Results:</strong> In 37 trials of pts with a history of CAD, BBs reduced CAD events 29% (95% CI: 22%, 34%). In 27 trials in which BBs were used after acute MI, BBs reduced CAD events 31% (95% CI: 24%–38%), and in 11 trials in which BBs were used after long-term CAD, BBs insignificantly reduced CAD events 13%. In 7 trials, BBs reduced stroke 17% (95% CI: 1%–30%). CAD events were reduced 14% (95% CI: 2%–25%) in 11 trials of thiazide diuretics, 17% (95% CI: 11%–22%) in 21 trials of ACEIs, insignificantly 14% in 4 trials of angiotensin receptor blockers, and 15% (95% CI: 8%–22%) in 22 trials of CCBs. Stroke was reduced 38% (95% CI: 28%–47%) in 10 trials of thiazide diuretics, 22% (95% CI: 8%–34%) in 13 trials of ACEIs, and 34% (95% CI: 25%–42%) in 9 trials of CCBs.</td>
<td>• With the exception of the extra protective effect of BBs given shortly after a MI and the minor additional effect of CCBs in preventing stroke, all the classes of BP-lowering drugs have a similar effect in reducing CAD events and stroke for a given reduction in BP.</td>
</tr>

### CAPRICORN

**Dargie HJ, et al., 2001 (141)**  
11356434

**Aim:** To investigate outcomes after carvedilol after MI in pts with LV dysfunction.

**Study type:** RCT  
**Size:** 1,959 pts  

**Inclusion criteria:** Pts ≥18 y, MI within 3–21 d of entry, LVEF ≤40%, concurrent ACEI stable dose for at least 24 h, HF pts treated and controlled with ACEI and diuretics but not inotropes.

**Exclusion criteria:** SBP <90 mm Hg, uncontrolled HTN, bradycardia, insulin-dependent DM, BBs not for HF, Beta-2 agonists, and steroids

**Intervention:** Carvedilol (975)  
**Comparator:** Placebo (984)

**1st endpoint:** All-cause mortality or hospital admissions for CV issues

**Results:** 12% vs. 15%; RR: 23% (95% CI: 0.60–0.98; p=0.03)

- No difference between groups for death or CV hospital admissions
- CV mortality, nonfatal MI reduced in the carvedilol group
- No difference between groups sudden death and admission due to HF

---

### Elkayam U, et al., 1990 (144)  
2242521

**Aim:** To assess comparative efficacy and safety of nifedipine and ISDN alone and the combination for treating for chronic CHF.

**Inclusion criteria:** 18–75 y old HF pts, NYHA class II and III, LVEF<40%, clinically stable, maintenance dose of Digitalis and diuretics.

**Exclusion criteria:** Pregnancy, nursing, history of MI ≤1 mo before entry, valvular disease, angina, significant pulmonary,

**Intervention:** Nifedipine (21), ISDN (20), Nifedipine+ISDN (23)  
**Comparator:** Placebo

**Endpoints and Results:**
- HF-worsening: 9 in Nifedipine group vs. 3 in ISDN group (p<0.09); and 21 in nifedipine-ISDN group (p<0.001 vs. nifedipine, p=0.0001 vs. ISDN)
- Clinical deterioration discontinuation:
- In clinical deterioration nifedipine pts (8) vs. rest of the pts (No difference in LVEF or VO2 max.)
- Although all the 3 drug regimens improved exercise capacity, nifedipine treatment alone or in combination resulted in clinical deterioration and worsening of CHF
### Study type: Crossover RCT
**Size:** 28 pts

**Inclusion criteria:** hepatic, renal and hematologic disease, unable to walk on the treadmill, noncompliance

**Intervention:** Nifedipine 29% vs. ISDN group 5% (p<0.05)

- **DBP:** Nifedipine alone or combination with ISDN (reduction, p<0.05)

**Follow-up Results:** Pts with BL EF<0.40, late CHF in Dilitazem group (21%) vs. Placebo (12%) p=0.004.

- Life table analysis confirmed increased frequency of late CHF in pts taking dilitiazem (p=0.0017)
- Dilitiazem related CHF exclusively associated with systolic LVD with or without BB s

### MDPIT
Goldstein RE, et al., 1991 (146) 1984898

**Aim:** To determine if dilitiazem increases late onset CHF in post-MI pts with early decline in EF.

**Study type:** RCT
**Size:** 2,466 pts

**Inclusion criteria:** 18–75 y HF pts, NYHA class II and III, LVEF <40%, clinically stable, maintenance dose of digitalis and diuretics.

**Exclusion criteria:** Pregnancy, nursing, history of MI <1 mo before entry, valvular disease, Angina, significant pulmonary, hepatic, renal and hematologic disease, unable to walk on the treadmill, noncompliance

**Intervention/Comparator:** Dilitiazem 240 mg (1,234) vs. Placebo (1,232)

**1ª endpoint and results:**
- HF-worsening: 9 in Nifedipine group vs. 3 in ISDN group (p<0.09); and 21 in nifedipine-ISDN group (p<0.001 vs. nifedipine, p<0.0001 vs. ISDN)
- Clinical deterioration discontinuation: Nifedipine 29% vs. ISDN group 5% (p<0.05)
- DBP: Nifedipine alone or combination with ISDN (reduction, p<0.05)

**Follow-up Results:** Pts with BL EF<0.40, late CHF in Dilitizam group (21%) vs. Placebo (12%) p=0.004.

- Treatment with valsartan resulted in improvements in NYHA class, LVEF, signs and symptoms of HF, and quality of life compared with placebo (p<0.01).

### SOLVD
Investigators, 1991 (153) 2057034

**Aim:** To determine the effect of enalapril vs. placebo on mortality plus morbidity in pts with HFrEF

**Inclusion criteria:** 2,569 pts, mean age 61 y, with NYHA class II-IV HF/CVF

**Intervention/Comparator:** 2,569 pts on standard therapy for HF were randomized to valsartan or placebo

**1ª endpoint and results:**
- At 41.4-mo follow-up, compared with placebo, enalapril reduced mortality by 16% (p=0.0036)

</table>
superior to ACE alone in the prevention of vascular events in pts with CVD or DM but not HF.

**Study type:** Multi-center, double-blind, RCT

**Size:** 25,620 pts

with end-organ damage

**Exclusion criteria:**
- Inability to discontinue ACEI or ARB
- Known hypersensitivity or intolerance to ACEI or ARB
- Selected CVDs (congestive HF, hemodynamically significant valvular or outflow tract obstruction, constrictive pericarditis, complex congenital heart disease, syncopal episodes of unknown etiology <3 mo, planned cardiac surgery or PTCA <3 mo, uncontrolled HTN on treatment [e.g., BP >160/100 mm Hg], heart transplant recipient, stroke due to subarachnoid hemorrhage)
- Other conditions (significant renal artery disease, hepatic dysfunction, uncorrected volume or sodium depletion, 1° hyperaldosteronism, hereditary fructose intolerance, other major noncardiac illness or expected to reduce life expectancy or significant disability interfere with study participation, simultaneously taking another experimental drug, unable to provide written informed consent).

- Telmisartan 80 mg daily (n=8,542)
- Combination of telmisartan and ramipril (n=8,502)

**Composite outcome of death from CV causes, MI, stroke, or hospitalization for HF (RR: 1.01; 95% CI: 0.94–1.09 and RR: 0.99; 95% CI: 0.92–1.07, respectively)**

**Safety endpoint:**
- Combination therapy was associated with greater risk of hyperkalemia than ramipril monotherapy (480 pts vs. 283 pts; p<0.001)
- Hypotensive symptoms were cited as reason for permanent discontinuing more in telmisartan vs. ramipril (RR: 1.54; p<0.001) and combination therapy vs. ramipril monotherapy (RR: 2.75; p<0.001)
- Renal impairment was more common in combination therapy vs. ramipril monotherapy (RR: 1.33; 95% CI: 1.22–1.44)

adverse events without an increase in benefit

### Aim: To determine the effect of antihypertensive drug therapy vs. placebo in prevention of HF in pts with isolated systolic HTN

**Inclusion criteria:** Pts ≥60 y with isolated systolic HTN in the SHEP program

**Intervention/Comparator:** 4,736 pts were randomized to antihypertensive drug therapy or placebo

**1° endpoint:** At 4.5-y follow-up, fatal or nonfatal HF was reduced 49% (p=0.001) by antihypertensive drug therapy (NNT to prevent 1 event =48)

**Relevant 2° endpoint:** CV mortality and nonfatal hospitalized HF was reduced 30% (p=0.002) by antihypertensive drug therapy

---

### Aim: To determine the effect of antihypertensive drug therapy on fatal or nonfatal stroke in pts ≥80 y

**Inclusion criteria:** Pts ≥80 y with a SBP≥160 mm Hg

**Intervention/Comparator:** 3,845 pts were randomized to antihypertensive drug therapy or placebo

**1° endpoint:** The 1° endpoint of fatal or nonfatal stroke was reduced 30% (p=0.06) by antihypertensive drug therapy

**Relevant 2° endpoint:** Antihypertensive drug therapy reduced HF 64% (p<0.001) all-cause mortality 21% (p=0.02), and CV death 23% (p=0.06)

---

### Summary: In pts with HF with preserved EF, spironolactone reduced the 1° endpoint of composite of CV death, aborted cardiac arrest, or HF hospitalization in the Americas group but not in the Russia/Georgia group. The pts enrolled in the Russia/Georgia group did not demonstrate either the expected morbidity and mortality associated with symptomatic HF with preserved EF or most pharmacological responses to spironolactone

---

**Aronow WS, et al., 1997 (162) 9230162**

**Inclusion criteria:** Pts ≥62 y with MI and LVEF ≥40% and HF NYHA class II or III treated with diuretics and ACEIs for 2 mo

**Intervention:** 79 pts were randomized to treatment with propranolol

**Comparator:** 79 pts were randomized to no propranolol.

- All pts continued diuretic and ACEI therapy.

**1° endpoint:** At 32-mo mean follow-up, multivariate Cox regression analysis showed that compared with no propranolol, propranolol reduced mortality 35% (p=0.03) and mortality plus nonfatal MI 37% (p=0.018)

**Relevant 2° endpoint:** At 1-y follow-up, LVEF was increased by propranolol from 57% to 63% (p<0.001) and LV mass was decreased by propranolol from 312 grams to 278 grams (p=0.001) Propranolol was stopped because of adverse effects in 11 of 79 pts (14%)

---

**Kostis JB, et al., 1997 (163) 9218667**

**Inclusion criteria:** Pts ≥60 y with isolated systolic HTN in the SHEP program

**Intervention/Comparator:** 4,736 pts were randomized to antihypertensive drug therapy or placebo

**1° endpoint:** The 1° endpoint of fatal or nonfatal stroke was reduced 30% (p=0.06) by antihypertensive drug therapy

---

**Beckett NS, et al., 2008 (164) 18378519**

**Inclusion criteria:** Pts ≥80 y with a SBP≥160 mm Hg

**Intervention/Comparator:** 3,845 pts were randomized to antihypertensive drug therapy or placebo

**1° endpoint:** The 1° endpoint of fatal or nonfatal stroke was reduced 30% (p=0.06) by antihypertensive drug therapy

| Law MR, et al., 2009 (18) 19454737   | **Study type:** Meta-analysis of use of BP-lowering drugs in prevention of CVD from 147 randomized trials  
**Size:** Of 147 randomized trials of 464,000 pts, 37 trials of BBs in CAD included 38,892 pts, and 37 trials of other antihypertensive drugs in CAD included 85,395 pts  
**Inclusion criteria:** The database search used Medline (1966–Dec. 2007 in any language) to identify randomized trials of BP-lowering drugs in which CAD events or strokes were recorded. The search also included the Cochrane Collaboration and Web of Science databases and the citations in trials and previous meta-analyses and review articles. | **1° endpoint:** CAD events; stroke  
**Results:** In 37 trials of pts with a history of CAD, BBs reduced CAD events 29% (95% CI: 22%, 34%). In 27 trials in which BBs were used after acute MI, BBs reduced CAD events 31% (95% CI: 24%, 38%), and in 11 trials in which BBs were used after long-term CAD, BBs insignificantly reduced CAD events 13%. In 7 trials, BBs reduced stroke 17% (95% CI: 1%–30%). CAD events were reduced 14% (95% CI: 2%–25%) in 11 trials of thiazide diuretics, 17% (95% CI: 11%–22%) in 21 trials of ACEIs, insignificantly 14% in 4 trials of angiotensin receptor blockers, and 15% (95% CI: 8%–22%) in 22 trials of CCBs. Stroke was reduced 38% (95% CI: 28%–47%) in 10 trials of CCBs. | • With the exception of the extra protective effect of BBs given shortly after a MI and the minor additional effect of CCBs in preventing stroke, all the classes of BP-lowering drugs have a similar effect in reducing CAD events and stroke for a given reduction in BP. |
### Exclusion criteria
Trials were excluded if there were <5 CAD events and strokes or if treatment duration was <6 mo.

Thiazide diuretics, 22% (95% CI: 8%–34%) in 13 trials of ACEIs, and 34% (95% CI: 25%–42%) in 9 trials of CCBs.

</tbody>
</table>
| REIN-2 | Aim: To determine whether intensive BP control will achieve further renoprotection (delayed progression to ESRD) compared to standard BP control in pts with chronic nephropathies  
Study type: Multicenter RCT of pts all placed on ACEI (ramipril) at maximum dose tolerated to achieve DBP <90 then assigned to conventional or intensified BP control. Add-on drug was dihydropyridine felodipine 5–10 mg/d  
Size: 335 (median time 19 mo) | Inclusion criteria:  
- Adults, age 18–70 y, with nondiabetic nephropathy, persistent proteinuria (urinary protein excretion >1 g/24 h for ≥3 mo) and not on ACEIs in previous 6 wk  
- Pts with proteinuria 1–3 g/24 h included if CrCl <70 mL/min/1.73 m²  
- For overall population, mean SBP, mm Hg (SD): Intensive: 137.0 (16.7)  
  conventional: 136.4 (17.0)  
- For overall population, mean DBP, mm Hg (SD): Intensive: 84.3 (9.0)  
  conventional: 83.9 (10.4)  
Exclusion criteria: Urinary tract infection, CHF class III–IV, treatment with corticosteroids, NSAIDs, immunosuppression, acute MI or stroke in prior 6 mo, severe uncontrolled HTN, | Intervention:  
- Intensive: BP goal <130/80 mm Hg  
- Conventional: DBP goal <90 mm Hg, irrespective of SBP  
- For baseline proteinuria subgroups, result BP values NR  
- For the overall population, achieved BP, mm Hg (SD)  
  Intensive: 129.6/79.5 (10.9/5.3)  
  Conventional: 133.7/82.3 (12.6/7.1)  
- Change in BP, mm Hg  
  Intensive: -7.4/-4.8  
  p=NR  
- BP difference between groups, mm Hg  
  Intensive: 4.1/2.8  
  p=NR  
1° endpoint  
- Time to ESRD; over 36 mo follow-up, median 19 mo  
1° outcome: ESRD in pts with baseline proteinuria 1–3 g/24 h  
  HR (95% CI): 1.06 (95% CI: 0.51–2.20)  
  p=0.89  
  ESRD in pts with baseline proteinuria >3 g/24 h  
  HR (95% CI): 1.09 (95% CI: 0.55–2.19)  
  p=0.81  
- 23% of intensive and 20% of conventional control groups progressed to ESRD.  
- Median rate of GFR decline, mL/min/1.73 m²/mo (IQR) in pts with baseline proteinuria <3 g/24:  
  Intensive: 0.18 (95% CI: 0.03–0.49)  
  p=0.21  
  Conventional: 0.39; 95% CI: 0.03–0.98  
  p=0.39  
- Median rate of GFR decline, mL/min/1.73 m²/mo (IQR) in pts with baseline proteinuria ≥3 g/24:  
  Intensive: 0.51; 95% CI: 0.16–1.05  
  p=0.39  
  Conventional: 0.39; 95% CI: 0.030.98  
  p=0.39  
Limitations: The study was stopped at the 1st interim analysis for futility. Median time 19 mo  
Summary: In pts with non-DM proteinuric nephropathies receiving background ACEI therapy, no additional benefits from further BP reduction by felodipine could be shown. Dihydropyridine CCBs do not offer additional renoprotection to ACEIs or ARBs. |

<tr>
<td><strong>Aim:</strong></td>
<td>To compare the effects of 2 levels of BP and 3 antihypertensive drug classes on GFR decline in HTN</td>
</tr>
</tbody>
</table>
| **Study type:** | • Randomized 3×2 factorial trial  
• Measured GFR with iothalamate |
| **Size:** | 1,094 |
| **Inclusion criteria:** | • Adult African-Americans, 18–70 y, with HTN (DBP ≥95) and GFR of 20–65 mL/min/1.73 m², no DM  
• At entry: mean MAP, mm Hg:  
  Low: 115 (27)  
  Usual: 113 (15)  
• Mean SBP, mm Hg (SD):  
  Low: 152 (25)  
  Usual: 149 (23)  
• Mean DBP, mm Hg:  
  Low: 96 (15)  
  Usual: 95 (14) |
| **Exclusion criteria:** | DBP < 95, history of DM, Urinary protein/creatinine ratio > 2.5, accelerated or malignant HTN, non-BP related cause of CKD, serious systemic disease, clinical CHF, specific indication or contraindication for a |
| **Intervention:** | • Low: MAP goal ≤92 mm Hg  
  Usual: MAP goal 102–107 mm Hg  
• Initial treatment with a B Blocker (metoprolol), and ACEI (ramipril) or a dihydropyridine (amlodipine) with open label agents added to achieve BP goals  
• Study duration: 3–6.4 y  
• BP similar across drug groups except 2 mm Hg lower in amlodipine group  
• Mean from 3 mo to study end  
• MAP, mm Hg (SD):  
  Low: 95.8 (8)  
  Usual: 104 (8)  
• SBP/DBP, mm Hg (SD):  
  Low: 128/78 (12/8)  
  Usual: 141/85 (12/7)  
• MAP change, mm Hg  
  Low: -20 |
| **1° endpoint:** | • 1° outcome: difference in mean slopes, acute GFR slope, mL/min/1.73 m²/3 mo (SE): 1.82 (0.54) in low BP group p<0.001  
• 1° outcome: difference in mean slopes, chronic GFR slope, mL/min/1.73 m²/y (SE): 0.21 (0.22) p=0.33 NS  
• Difference in mean slopes, total GFR slope, mL/min/1.73 m²/y (SE): -0.25 (0.22) p=0.24  
• Main 2° clinical composite outcome: GFR event, ESRD, or death, % risk reduction (95% CI): 2 (95% CI: -22–21) p=0.85  
• GFR event or ESRD, % Risk Reduction: -2; 95% CI: -31–20; p=0.87  
• ESRD or death, % risk reduction: 12; 95% CI: -13–32; p=0.31  
• ESRD alone, % risk reduction: 6; 95% CI: -29–31; p=0.72 |
| **Limitations:** | • Based on DSMD recommendation, amlodipine arm halted early and those pts switched to open label Rx, continued study schedule and same BP goals |
| **Summary:** | • No difference in GFR decline with lower BP goal and no difference in composite clinical endpoints  
• Average rate of GFR decline 2 mL/min/y is similar or slower than previous reports  
• There was a trend favoring the lower BP goal in subjects with higher baseline proteinuria and the opposite trend for those without proteinuria  
• Ramipril treatment group had slower progression compared with metoprolol and amlodipine combined, less evident between ramipril and metoprolol |

### Amlodipine Versus Enalapril in Renal Failure (AVER trial)
Esnault VL, et al., 2008 (175)  
18405787

#### Aim:
To compare GFR decline in nondiabetic, nonnephrotic adults with HTN and estimated CrCl 20–60 mL/min/1.73 m² when randomized to a CCB (amlodipine, 5–10 mg/d) or an ACEI (enalapril, 5–20 mg/d).

#### Study type: RCT

#### Size:
- Amlodipine: 132
- Enalapril: 131

#### Inclusion criteria:
- 18–80 y
- CrCl 20–60 mL/min/1.73 m² (Cockcroft-Gault)
- Nondiabetic
- Enrollment confirmed at end of 4-wk placebo run-in if sitting DBP between 90 and 119 mm Hg
- Mean SBP, mm Hg (SD): Amlodipine: 165.1 (15.4) Enalapril: 165.2 (16.6)
- Mean DBP, mm Hg (SD): Amlodipine: 102.0 (6.7) Enalapril: 102.5 (7.1)
- Mean serum Cr, mg/dl (SD): Amlodipine: 2.00 (0.8) Enalapril: 2.05 (0.7)

#### Exclusion criteria:
- Nephrotic proteinuria
- 2º or malignant HTN (DBP >120 mm Hg)
- A major CV event within 3 mo
- Angina pectoris
- Congestive heart disease (NYHA II-IV)
- Uncontrolled arrhythmias
- II-III AV block
- Need for serious steroids, NSAIDS or cytotoxic drugs

#### Intervention:
- Amlodipine: 5–10 mg/d
- Enalapril: 5–20 mg/d
   - Therapy initiated with amlodipine 5 mg/d or enalapril 5 mg/d. Drugs up-titrated to amlodipine 10 mg/d or enalapril 20 mg/d at wk 8 and 12 if DBP >90 mm Hg.
   - After 18 wk, if maximal tolerated dose of study drug did not decrease BP to target, add on anti-HTN treatments were the following: atenolol (50–100 mg/d), loop diuretics (furosemide 20–500 mg/d or torsemide, 5–200 mg/d), alpha blockers (prazosin, 2.4–5 mg/d or doxazosin, 1–16 mg/d) and centrally acting drugs (rilmenidine (1–2 mg/d or methyldopa, 250–500 mg/d).

- BP goal:
  - Amlodipine: <130/85 mm Hg
  - Enalapril: <130/85 mm Hg

- Duration of treatment:
  - Median follow-up 2.93 y in amlodipine group; 2.95 y in enalapril group

#### 1º endpoint: Change in GFR from baseline to final assessment

#### 2º Outcome: Clinical composite of renal replacement therapy, discontinuation due to deterioration of renal function, 50% decrease in GFR, doubling of serum Cr, hospitalization for transient renal failure. "Other 2º outcome measures" included: changes in serum Cr, sitting DBP and SBP, heart rate, total and HDL cholesterol, 24-h urinary protein excretion, ambulatory BP monitoring, and safety measures.

#### Composite Outcomes: 2º clinical composite

#### Safety endpoint:
Proteinuria subgroup, >1 g/d: protein excretion rate decreased significantly in pts taking enalapril plus diuretic (median -270 mg/d; p<0.001) but not in pts taking amlodipine plus diuretic (-25 mg/d) at last obs

#### Summary:
- No difference in GFR change or serum creatinine at trial end
- Last observation: mean change in GFR, mL/min/1.73 m²: Amlodipine -4.92, Enalapril -3.98; p=NS
- Last observation: mean change in Serum Cr from baseline (mg/dl): Amlodipine +0.57, Enalapril +0.47; p=NS
- No difference in composite 2º endpoints.
- Mean BP (mm Hg): baseline to last observation Amlodipine 164.8/101.8 to 140.1/85.4, delta -24.7/16.4 Enalapril 165.0/102.5 to 140.3/86.4, delta -24.7/16.1

#### Usual: 15 (0.006); p=NS

#### No difference in composite 2º endpoints.
Aim: To investigate in a random comparison the capacity of an angiotensin converting enzyme inhibitor (fosinopril), and that of a long-acting dihydropiridine (nifedipine GITS) to modify the decay in renal function in pts with primary renal disease, exhibiting a progressive increase in serum Cr during the previous 2 y.

Study type: Randomized open label trial

Size: 241
Nifedipine GITS: 112
Fosinopril: 129

Inclusion criteria:
- 18–75 y
- Serum Cr between 1.5 and 5 mg/dL (133–442 µmol/l)
- HTN defined as BP >140/90 mm Hg or by the use of antihypertensive agent(s)
- Proven progression of chronic renal failure in the previous 2 y, defined by increase by >25% or >0.5 mg/dL (44.2 µmol/l) in serum Cr
- Mean SBP, mm Hg (SD):
  - Nifedipine GITS: 157.5 (20)
  - Fosinopril: 155 (17)
- Mean DBP, mm Hg (SD):
  - Nifedipine GITS: 96 (11)
  - Fosinopril: 96 (8)

Exclusion criteria:
- DM
- Previous recent history of CVD (stroke, MI, or HF)
- Taking concomitant medications that could limit the ability of pts to comply with protocol requirements

Intervention:
- Nifedipine GITS: 30–60 mg QD
- Fosinopril: 10–30 mg QD
- Drugs added in step-wise fashion to achieve BP goal.
  - Step 1: Randomized drug
  - Step 2: Furosemide (up to 100 mg)
  - Step 3: Atenolol (up to 100 mg)
  - Step 4: Doxazosin (up to 12 mg)
- BP goal:
  - Nifedipine GITS: <140/90 mm Hg
  - Fosinopril: <140/90 mm Hg
- Duration of treatment: mean follow-up NR; authors report minimum follow-up of 3 y and this is when most outcome measures reported

1° endpoint:
- 1° Outcome: Time elapsed until serum Cr values doubled, or the need to enter a dialysis program
- 2° Outcome: CV events (including MI, stroke, angina, and death), proteinuria evolution and serum Cr

Safety endpoint: N/A

Limitations:
- SBP was 4–6 mm Hg lower with ACEI which may have impacted improved outcomes. Still positive effects remained from fosinopril after adjusted for BP levels.
- Sodium restriction may have favored the ACEI group.

Summary:
- Renal survival was significantly better if fosinopril used as first agent, unrelated to the primary renal disease.
- Proteinuria decreased by 57% in the fosinopril group and increased by 7% in the nifedipine GITS group while BP control did not differ between treatment groups for DBP.
- 3-y follow-up Doubling of serum Cr or entering dialysis N (%)
  - Nifedipine GITS 40 (36%)
  - Fosinopril 27 (21%)
  - OR: 0.47 (0.26–0.84); p=0.01
- Decrease in SBP, mm Hg (SD)
  - Nifedipine GITS 40 (36%)
  - Fosinopril 27 (21%)
  - OR: 0.47 (0.26–0.84); p=0.01
- Decrease in DBP, mm Hg (SD)
  - Nifedipine GITS 14.0 (22.5)
  - Fosinopril 19.8 (19.6), p NR
### ACCOMPLISH

**Bakris GL, et al., 2010 (177)**

**Aim:** To examine the effect of initial antihypertensive therapy with benazepril plus amlodipine compared to benazepril plus hydrochlorothiazide on progression of CKD

**Study type:** RCT, forced drug titration

**Size:**
- Overall benazepril plus amlodipine: n=5,744
- Benazepril plus hydrochlorothiazide: n=5,762
- Pts with CKD:
  - Benazepril plus amlodipine: n=561
  - Benazepril plus hydrochlorothiazide: n=532
- Pts without CKD:
  - Benazepril plus amlodipine: n=5,171
  - Benazepril plus hydrochlorothiazide: n=5,218

**Inclusion criteria:**
- Males or females ≥55 y, with HTN, high CV risk (history of coronary events, MI, revascularization, stroke, CKD, PAD, LVH, DM)
- Entry BP for pts with CKD:
  - Benazepril plus amlodipine: 145.1/78.6 (20.2/11.2)
  - Benazepril plus hydrochlorothiazide: 145.0/78.1 (20.5/10.7)

**Exclusion criteria:**
- N/A

**Intervention:**
- Initial antihypertensive therapy with benazepril plus amlodipine compared to benazepril plus hydrochlorothiazide
- BP after dose adjustment:
  - Benazepril plus amlodipine: 131.6/73.3 (18.2/10.3 SD)
  - Benazepril plus hydrochlorothiazide: 132.5/74.4 (17.9/11.2 SD)

**Comparator:**
- N/A

**1° endpoint:**
- Overall: time to first event of composite CV morbidity and mortality
- Progression of CKD, a prespecified endpoint, was defined as doubling of serum creatinine concentration or ESRD (estimated glomerular filtration rate <15 mL/min/1.73 m² or need for dialysis).
- All randomized pts were included in the intention-to-treat analysis. There were 113 (2.0% x 0%) events of CKD progression in the benazepril plus amlodipine group compared with 215 (3.7% x 7%) in the benazepril plus hydrochlorothiazide group HR: 0.52, (95% CI: 0.41–0.65), p<0.0001

**2° endpoints:**
- CKD plus death, change in albuminuria, change in eGFR
- Subset with more advanced CKD analyzed for rate of progression

**Safety endpoint:**
- N/A

**Limitations:**
- Trial terminated early (mean follow-up 2.9 y [SD 0.4]) because of superior efficacy of benazepril plus amlodipine compared with benazepril plus hydrochlorothiazide with 20% lower CV risk.
- Very small proportion of study population had albuminuria above 33.9 mg/mmol combined with early trial termination to reduce renal events.
- Funded by Novartis.

**Summary:**
- Initial antihypertensive treatment with benazepril plus amlodipine slowed progression of nephropathy to a greater extent compared to benazepril plus hydrochlorothiazide.

### AVOID

**Parving HH, et al., 20170948**

**Aim:** Compare effects of dual blockade of

**Inclusion criteria:**
- Pts with HTN, 18–85 y, on losartan then aliskiren or

**Intervention:**
- All on losartan then aliskiren or

**1° endpoint:**
- Ratio of albumin to creatinine at 6 mo

**Limitations:**
- No renal endpoints regarding function, survival, CV
| Study | RAAS by aliskiren 300 mg/d added to maximal dose losartan 100 mg/d and optimal HTN therapy | and DM-2 and nephropathy (early morning alb/creat >300 mg/g or >200 mg/g in on RAAS blocker already | placebo added | Comparator: All on losartan, aliskiren or placebo added | 2\(^{-}\) endpoint: decline in eGFR, development of renal dysfunction (serum creatinine >176.8 micromol/l (2.0 mg/dL)

**Safety endpoint:** Hyperkalemia 5\% in aliskiren group, 5.7\% in placebo group but more frequent individual elevations >5.5 in aliskiren group | events, BP 2/1 mm Hg lower in aliskiren group; supported by Novartis

**Summary:**
- Outcome was degree of albuminuria. Aliskiren reduced urinary alb/creat ratio by 20\% (95\% CI 9–30; \(p<0.001\))
- From post hoc analysis: Antiproteinuric effects consistent across CKD stages (19\%, 22\%, and 18\% for stages 3, 2, and 1).
- For CKD 3, renal dysfunction more frequent in placebo group (29.3 vs. 13.6\%; \(p=0.032\))
- No differences in deaths or acute renal failure by treatment group (0.7\% in both)

| Study | VA NEPHRON-D Fried LF, et al., 2010 (124) | Inclusion criteria: Pts without adverse events on full dose losartan DM-2, eGFR 30–89.9 mL/min/1.73 m\(^2\) by 4 variable MDRD formula, urinary albumin/creatinine ratio of ≥300 in a random sample | Intervention: Pts with DM-2 already taking losartan 100 mg/d with albumin to creatinine ratio of ≥300 were randomized to either lisinopril 10–40 mg/d or placebo. Pts with DM-2 already taking losartan 100 mg/d with albumin to creatinine ratio of ≥300 were randomized to either lisinopril 10–40 mg/d or placebo.

**1\(^{-}\) endpoint:** First occurrence of a change in eGFR (a decline of ≥30 mL/min/1.73 m\(^2\) if initial GFR ≥60 or a decline of ≥50% if initial eGFR <60, ESRD or death

**2\(^{-}\) endpoint:** First occurrence of decline in eGFR or ESRD

**Safety endpoint:** mortality, hyperkalemia, acute kidney injury | Study stopped early due to safety concerns. Combination of ACEI and ARB was associated with increased risk of adverse events among pts with diabetic nephropathy |
### Data Supplement 38. Nonrandomized Trials, Observational Studies, and/or Registries of CKD (Section 9.3)

</table>
| Upadhyay A, et al., 2011 (1/79) 21403055 | Aim: To summarize trials comparing lower vs. higher BP targets in pts with CKD; focus on proteinuria as an effect modifier  
Study type: Systematic review  
Size: 2,272 | Inclusion criteria: >50 pts/group, 1 y follow-up, outcomes of death, kidney failure, CV events, change in kidney function, number of antihypertensive agents, adverse events.  
3 trials (MDRD, AASK, REIN-2; 8 reports) | Results: Overall trials did not show that BP target of <125/75–130/80 is more beneficial than a target of <140/90. Lower quality evidence suggests a low target may be beneficial in subgroups with proteinuria >300–1,000/d | Limitations: No pts with DM-1 included. Duration (mean follow-up 2–4 y) may be too short to detect differences in clinically important outcomes. Reporting of adverse events not uniform.  
Summary: Available evidence is inconclusive but does not prove a BP target <130/80 improves clinical outcomes more than a target of <140/90 in adults with CKD. |
| Lv, et al., 2013 (1/27) 23798459 | Aim: To assess the renal and CV effects of intensive BP lowering in people with CKD  
Study type: Systematic review  
Size: 9,287 pts with CKD and 1,264 kidney failure events | Inclusion criteria:  
• Randomized trials of pts with CKD assigned to different target BP that reported kidney failure and CV events.  
• 11 trials on 9,287 pts with CKD and 1,264 kidney failure events (doubling of serum creatinine, 50% decline in GFR or ESKD)  
• Included AASK, REIN-2, MDRD, Wuhl (children), Toto, Schrier plus 5 trials with CKD subgroups, also included the late nonrandomized follow-up studies for AASK and MDRD  
• BP targets varied substantially between trials. 2 trials targeted mean BP <92 mm Hg for the intensive treatment arm, and 107 mm Hg in the standard treatment arm. 1 trial aimed for BP<130/80 mm Hg vs. a DBP of 90 mm Hg, 1 study targeted <120/80 mm Hg vs. | Results: Compared with standard regimens, more intensive BP lowering reduced risk of composite endpoint HR: 0.82; 95% CI: 0.68–0.98, and ESKD HR: 0.79; 95% CI: 0.67–0.93. Effect was modified by proteinuria (p=0.006) and markers of trial quality. Intensive BP lowering reduced the risk of kidney failure HR: 0.73; 95% CI: 0.62–0.86 but not in pts without proteinuria at baseline HR: 1.12; 95% CI: 0.67–1.87. No clear effect on CV events or death. | Limitations: All trials used open label, in 2 pts were blinded, substantial variability in design quality. There was substantial variability in BP targets by MAP, systolic and DBP or only DBP. Most trials did not include pts with diabetic kidney disease  
Summary:  
• Renal outcomes: 7 trials (N=5,308) recorded a total of 1,264 kidney failure events. A -7.7 mm Hg difference in SBP and a -4.9 mm Hg difference in DBP seen between treatment arms. Overall, a more intensive regimen reduced risk of composite kidney failure events by 17% HR: 0.82; 95% CI: 0.68–0.98, reduced the risk of ESKD alone by 18% (pooled HR for composite outcomes: 0.79; 95% CI: 0.67–0.93).  
• Intensive BP lowering had no effect on kidney failure in pts who did not have proteinuria (3 trials involving 1,218 pts HR: 1.12; 95% CI: 0.67–1.87), but it did reduce the risk of progressive kidney failure by 27% (5 trials involving 1,703 pts HR: 0.73; 95% CI: 0.62–0.86) in people who did have proteinuria at baseline. |
| Jafar TH, et al., 2003 (180) | **Aim:** To determine the levels of BP and urine protein excretion associated with lowest risk for progression of CKD during antihypertensive therapy with and without ACEIs.  
**Study type:** 11 RCTs in pts with predominantly non-diabetic kidney disease  
**Size:** 1,860 pooled in pt level meta-analysis; mean duration of follow-up 2.2 y | **Inclusion criteria:**  
- Pt-level meta-analysis using data from the AIPRD Study Group database to assess relationships among pts with non-diabetic kidney disease across a wide range of urine protein excretion values during antihypertensive therapy with and without ACEIs.  
- The AIPRD Study Group database included 1,860 pts with non-diabetic kidney disease enrolled in 11 RCTs of ACEIs to slow the progression of kidney disease. The database contained information on BP, urine protein excretion, serum creatinine, and onset of kidney failure during 22,610 visits.  
- Included only randomized trials (with a minimum 1 y follow-up) that compared the effects of antihypertensive regimens that included ACEIs with the effects of regimens that did not include ACEIs. HTN or decreased kidney function was required for entry into all studies.  
**Exclusion criteria:** Common to all studies: acute kidney failure, treatment with immunosuppressive meds, clinically significant chronic HF, obstructive uropathy, renal artery stenosis, active systemic disease, DM-1, history of transplantation, history of allergy to | **1st endpoint:** Progression of CKD defined as doubling of serum creatinine or onset of kidney failure  

- **Results:** Kidney disease progression documented in 311 pts, 124 (13.2%) in the ACEI group and 187 (20.5%) in the control group (p=0.001). 176 (9.5%) developed kidney failure: 70 (7.4%) in the ACEI group and 106 (11.6%) in the control group (p=0.002). SBP of 110–129 mm Hg and urine protein excretion <2.0 g/d were associated with lowest risk for kidney disease progression. ACEI beneficial after adjustment for BP and urine protein excretion (RR: 0.67; 95% CI: 0.53–0.84). The increased risk for kidney progression at higher SBP levels was greater in pts with urine protein excretion >1.0 g/d (p<0.006).  
  | **Limitations:** Studies included were not designed to assess the effect of lowering BP and urine protein excretion on kidney disease progression.  
**Conclusions:** Although reverse causation cannot be excluded with certainty, SBP goal between 110 and 129 mm Hg may be beneficial in pts with urine protein excretion >1.0 g/d. SBP <110 mm Hg may be associated with higher risk for kidney disease progression. |
### Giatras I, et al., 1997 (181)

| **Aim:** To use meta-analysis to assess effects if ACEIs on development of ESRD in nondiabetic pts |
| **Study type:** Meta-analysis |
| **Size:** 1,594 pts from 10 studies |

**Inclusion criteria:** All randomized studies comparing ACEIs with other antihypertensive agents, with at least 1 y of follow-up

**Exclusion criteria:** Studies of diabetic renal disease and renal transplants were excluded.

**Results:**
- Among 806 pts receiving ACEIs, 52 (6.4%) developed ESRD and 17 (2.1%) died.
- In 788 controls, 72 (9.1%) developed ESRD and 12 (1.5%) died. The pooled RR were 0.70; 95% CI: 0.51–0.97 for ESRD and 1.24; CI: 0.55–2.83 for death.
- The decreases in weighted mean systolic and DBPs during follow-up were 4.9 and 1.2 mm Hg greater, respectively, in the pts who received ACEIs.

**Limitations:** Included studies through 5/1996, published (7) and nonpublished (3) study results. Did not require that pts have HTN or renal insufficiency at baseline. Did not report results by severity of proteinuria related to the diseases included many of which are not characterized by proteinuria.

**Summary:** ACEIs are more effective than other antihypertensive agents in reducing the development of end-stage nondiabetic renal disease, and they do not increase mortality. It could not be determined whether this beneficial effect is due to the greater decline in BP or to other effects of ACE inhibition.

### ONTARGET Investigators, et al., 2008 (126)

| **Aim:** Evaluate whether use of an ARB was noninferior to ACEI, and whether the combination was superior to ACEI alone in the prevention of vascular events in pts with CVD or DM but not HF. |
| **Study type:** Multi-center, double-blind, RCT |
| **Size:** 25,620 pts |

**Inclusion criteria:**
- ≥55 y
- Coronary, peripheral, or cerebrovascular disease or DM with end-organ damage

**Exclusion criteria:**
- Inability to discontinue ACEI or ARB
- Known hypersensitivity or intolerance to ACEI or ARB
- Selected CVDs (congestive HF, hemodynamically significant valvular or outflow tract obstruction, constrictive pericarditis, complex congenital heart disease, syncopal episodes of unknown etiology <3 mo, planned cardiac surgery or PTCA <3 mo, uncontrolled HTN on treatment [e.g., BP >160/100 mm Hg], heart transplant recipient, stroke due to subarachnoid hemorrhage)
- Other conditions (significant renal artery disease, hepatic dysfunction, uncorrected volume or sodium depletion,

**Intervention:** Ramipril 10 mg daily (n=8,576)

**Comparator:**
- Telmisartan 80 mg daily (n=8,542)
- Combination of telmisartan and ramipril (n=8,502)

**1° endpoint:** After a median follow-up of 56 mo, there was no difference between ramipril vs. telmisartan or combination therapy vs. ramipril in the 1° composite outcome of death from CV causes, MI, stroke, or hospitalization for HF RR: 1.01; 95% CI: 0.94–1.09 and RR: 0.99; 95% CI: 0.92–1.07, respectively

**Safety endpoint:**
- Combination therapy was associated with greater risk of hyperkalemia than ramipril monotherapy (480 pts vs. 283 pts; p<0.001)
- Hypotensive symptoms were cited as reason for permanent discontinuing more in telmisartan vs. ramipril RR: 1.54; p<0.001 and combination therapy vs. ramipril monotherapy RR: 2.75; p<0.001
- Renal impairment was more common in combination therapy vs. ramipril monotherapy RR: 1.33; 95% CI: 1.22–1.44).
### VALIANT

**White HD, et al., 2005 (182)**

### Aim:
Evaluate whether use of an ARB or the combination of an ACEI and an ARB was superior to a proven effective dose of an ACEI after AMI in pts with HF and/or LVEF <40%.

### Study type:
Multi-center, double-blind, RCT

### Size:
14,703 pts

### Inclusion criteria:
- ≥18 y
- Between 12 h and 10 d after AMI
- Clinical or radiological signs of HF and/or evidence of depressed LV systolic function with EF<40% or reduced echo wall motion index

### Exclusion criteria:
- Cardiogenic shock
- Serum creatinine >2.5 mg/dL
- Known hypersensitivity or intolerance to ACEI or ARB
- SBP<100 mm Hg
- Known or suspected bilateral renal artery stenosis
- Stroke or TIA within previous 3 mo
- Refractory ventricular arrhythmia
- Refractory angina
- Right ventricular MI
- Mitral stenosis, mitral regurgitation, aortic stenosis, aortic regurgitation of hemodynamic significance
- Obstructive cardiomyopathy
- Previous major organ transplant
- Conditions likely to lead to poor adherence

### Intervention:
Valsartan 160 mg bid

### Comparator:
- Captopril 50 mg tid
- Combination of captopril 50 mg tid and valsartan 160 mg bid

### Safety endpoint:
- Adverse events associated with captopril and valsartan were more common in the elderly and in pts receiving combination therapy.
- Renal dysfunction was more common with older age and combination therapy.

### 1° endpoint:
All-cause mortality

### 2° endpoint:
- Composite of CV mortality or emergency treatment or hospitalization for new or worsening HF, reinfarction, stroke, and resuscitated cardiac arrest
- On 3-y multivariable analysis, each 10-y age increase was associated with HR: 1.49; 95% CI: 1.43–1.56); p<0.0001 for mortality and an OR: 1.38; 95% CI: 1.31–1.46; p<0.0001 for readmission with HF.
- Similar but slightly smaller trend for composite endpoint, higher mainly in the oldest group.

Valsartan was at least as effective as captopril in reducing mortality and other adverse outcomes in all age groups and combination therapy with both agents added no incremental benefit.

Combination therapy increased the incidence of adverse effects leading to discontinuation in all age groups.
## Data Supplement 39. RCTs Comparing Hypertension after Renal Transplantation (Section 9.3.1)

</table>
| Cross NB, et al., 2009 (187) 19588343| Study type: Comparative assessment by drug class using RCTs and quasi-RCTs lasting at least 2 wk in kidney transplant pts  
**Size:**  
- 60 studies, 3,802 pts, most taking cyclosporine based immunosuppression  
- 29 studies (n=2,262) compared CCB to placebo, 10 (n=445) ACEI to placebo, 7 (n=405) CCB to ACEI | **Inclusion criteria:** 21 studies for HTN, 6 for erythrocytosis, 2 CAN, 2 LVH, 30 not specified  
**Exclusion criteria:** N/A | **1ª endpoint:** To assess comparative effects of antihypertensive agents in kidney transplant pts  
**Results:** Used random effects meta-analysis, risk ratios for dichotomous outcomes and MD for continuous outcomes, both with 95% CI. Stratified analyses and meta-regression to investigate heterogeneity.  
- CCBs vs. placebo or no treatment had strongest results: improved GFR MD: 4.45 mL min (95% CI: 2.22–6.68), reduced graft loss RR: 0.75, (95% CI: 0.57–0.99).  
- ACEI vs. placebo inconclusive for GFR MD: -8.07 mL/min (95% CI: -18.57–2.43) and variable for graft loss.  
- Compared to CCB, ACEI decreased GFR MD: -11.48 mL/min; 95% CI: -5.75--7.21), proteinuria MD: -0.28 g/24 h (95% CI: -0.47--0.10), also reduced hemoglobin MD: -12.96 g/L (95% CI: -5.72--10.21) and increased hyperkalemia RR: 3.74 (95% CI: 1.89--7.43). Graft loss data were inconclusive.  
- CCB may be preferred as first line for HTN after kidney transplant. ACEI may have some detrimental effects. There were not enough studies with other agents. | |
| Jennings DL, et al., 2008 (188) 18094340| Study type: Literature review  
**Size:** 5 studies with 3 reporting safety endpoints and 2 reporting clinical efficacy endpoints | **Inclusion criteria:** Studies using either ACEI or ARB initiated within the first 12 wk after renal transplant | **1ª endpoint:** Safety or efficacy  
**Results:**  
- No significant increase in serum creatinine or potassium after up to 9 mo Rx  
- Early initiation of ACEI may be more effective than BB in reducing LVH and proteinuria after 24 mo treatment | **Conclusion:** Reasonable to consider RAAS inhibitors as first-line treatment in pts with HTN and compelling indications i.e., DM, HF in first 12 wk after renal transplant. |
| Ninomiya T, et al., 2013 (189) 24092942| Aim: To define CV effects of lowering BP in pts with CKD  
**Study type:** | **Inclusion criteria:** Had to meet 1 of the following criteria: Pts randomized to a BP-lowering drug/regimen or a control group (placebo or less intensive BP lowering regimen) or pts randomized | **Results:** Compared with placebo, BP lowering regimens reduced the risk of major CV events by about a sixth per 5 mm Hg reduction in SBP in individuals with (HR: 0.83; 95% CI) | **Limitations:**  
- Limited numbers with CKD and most were stage 3a:  
- There were 121,995 pts (80%) with eGFR ≥60 mL/min/1.73 m² (mean eGFR 81 (SD 17)
Meta-analysis of RCTs

• Individual pt data available for 23 trials, with summary data from another 3. Meta-analysis was performed according to baseline kidney function.

**Size:** 26 trials (152,290 pts), including 30,295 pts with reduced eGFR, defined as eGFR <60 mL/min/1.73 m².

between regimens based on different classes of drugs to lower BP. Trials required to have at least 1,000 pt-y of planned follow-up in each randomized arm and not to have presented or published their main results before finalization of the overview protocol in July 1995.

**Exclusion criteria:** Trials prior to July 1995.

<table>
<thead>
<tr>
<th>Intervention: Ramipril 10 mg daily (n=8,576)</th>
<th>Comparator: Telmisartan 80 mg daily (n=8,542) Combination of telmisartan and ramipril (n=8,502)</th>
</tr>
</thead>
</table>

0.76–0.90) and without reduced eGFR (HR: 0.83; 95% CI: 0.79–0.88), with no evidence for any difference in effect (p=1.00 for homogeneity). The results were similar irrespective of whether BP was reduced by regimens based on ACEIs, calcium antagonists, or diuretics/BBs. There was no evidence that the effects of different drug classes on major CV events varied between pts with different eGFR (all p>0.60 for homogeneity).

Summary:

• These analyses provided compelling evidence for the CV benefits of reduction in BP in pts with stage 1–3 CKD. The proportional reductions in risk of major CV events were similar in pts with and without evidence of CKD, however those with CKD stood to gain larger absolute benefits because their baseline risk was much higher.

• BP-lowering is an effective strategy for preventing CV events among pts with moderately reduced eGFR. There is little evidence from these overviews to support the preferential choice of particular drug classes for the prevention of CV events in CKD.

**ONTARGET Investigators, et al., 2008 (126)**

**Aim:** Evaluate whether use of an ARB was noninferior to ACEI, and whether the combination was superior to ACE alone in the prevention of vascular events in pts with CVD or DM but not HF.

**Study type:** Multi-center, double-blind, RCT

**Size:** 25,620

**Inclusion criteria:**

- ≥55 y
- Coronary, peripheral, or cerebrovascular disease or DM with end-organ damage

**Exclusion criteria:**

- Inability to discontinue ACEI or ARB
- Known hypersensitivity or intolerance to ACEI or ARB
- Selected CVDs (congestive HF, hemodynamically significant valvular or outflow tract obstruction, constrictive pericarditis, complex congenital heart disease, syncopal episodes of unknown etiology <3 mo, planned cardiac surgery or PTCA <3 mo, uncontrolled HTN on treatment [e.g., BP >160/100 mm Hg], heart transplant recipient,

<table>
<thead>
<tr>
<th>1° endpoint: After a median follow-up of 56 mo, no difference between ramipril vs. telmisartan or combination therapy vs. ramipril in the 1° composite outcome of death from CV causes, MI, stroke, or hospitalization for HF: RR: 1.01 (95% CI: 0.94–1.09) and RR: 0.99 (95% CI: 0.92–1.07), respectively.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Safety endpoint: Combination therapy was associated with greater risk of hyperkalemia than ramipril monotherapy (480 pts vs. 283 pts; p&lt;0.001)</th>
</tr>
</thead>
</table>

- Hypotensive symptoms were cited as reason for permanent discontinuing more in telmisartan vs. ramipril RR: 1.54, p<0.001; and combination therapy vs. ramipril monotherapy RR: 2.75, p<0.001
- Renal impairment was more common in combination therapy vs. ramipril monotherapy RR: 1.33; 95% CI: 1.22–1.44
| VALIANT | **Aim:** Evaluate whether use of an ARB or the combination of an ACEI and an ARB was superior to a proven effective dose of an ACEI after AMI in pts with HF and/or LVEF <40%.  
**Study type:** Multi-center, double-blind, RCT  
**Size:** 14,703 | **Inclusion criteria:**  
- ≥18 y  
- Between 12 h and 10 d after AMI  
- Clinical or radiological signs of HF and/or evidence of depressed LV systolic function with EF<40% or reduced echo wall motion index  
**Exclusion criteria:**  
- Cardiogenic shock  
- Serum creatinine >2.5 mg/dL  
- Known hypersensitivity or intolerance to ACEI or ARB  
- SBP<100 mm Hg  
- Known or suspected bilateral renal artery stenosis  
- Stroke or TIA within previous 3 mo  
- Refractory ventricular arrhythmia  
- Refractory angina  
- Right ventricular MI  
- Mitral stenosis, mitral regurgitation, aortic stenosis, aortic regurgitation of hemodynamic significance  
- Obstructive cardiomyopathy  
- Previous major organ transplant  
\[\text{Intervention: Valsartan 160 mg bid}\]  
**Comparator:**  
- Captopril 50 mg tid  
- Combination of captopril 50 mg tid and valsartan 160 mg bid  
- Analyzed by prespecified age groups of <65 (n=6,988)  
65 to 74 (n=4,555)  
75 to 84 (n=2,777)  
≥85 y (n=383)  

1° **endpoint:** All-cause mortality  
2° **endpoint:**  
- Composite of CV mortality or emergency treatment or hospitalization for new or worsening HF, reinfarction, stroke, and resuscitated cardiac arrest  
- On 3-y multivariable analysis, each 10-y increase was associated with HR: 1.49 (95% CI: 1.43–1.56), p<0.0001 for mortality and OR: 1.38 (95% CI: 1.31–1.46; p<0.0001) for readmission with HF.  
- Similar but slightly smaller trend for composite endpoint, higher mainly in the oldest group. Valsartan was at least as effective as captopril in reducing mortality and other adverse outcomes in all age groups and combination therapy with both agents added no incremental benefit. Combination therapy increased the incidence of adverse effects leading to discontinuation in all age groups  
**Safety endpoint:**  
- Adverse events associated with captopril and valsartan were more common in the elderly and in pts receiving combination therapy.  
- Renal dysfunction was more common with older age and combination therapy.
Conditions likely to lead to poor adherence

### SPRINT Senior Williamson JD, et al., 2016 (190) 27195814

**Aim:** Intensive SBP goal <120 mm Hg) vs. standard (SBP goal <140)

**Study type:** RCT

**Size:** 2,636; 30% met criteria for being classified as ambulatory frail

**Mean follow-up:** 3.1 y

**Inclusion criteria:** Men and women age 75+; mean age 79.8 y; 38% women; 17% black, 74% Caucasian

**Exclusion criteria:** Nursing home residents; prevalent DM, stroke, Class III/IV HF, dementia

**Intervention:** Medications and dietary advice to achieve SBP of <120 mm Hg

**Comparator:** Medications and dietary advice to achieve SBP of <140 mm Hg

**Achieved SBP:** Intensive=123.4 mm Hg Standard=134.8 mm Hg

**1° endpoint:** Composite CVD outcome (AMI, non-MI ACS, Stroke, HF, CVD death)

**Results:**
- 102 events in the intensive treatment group vs. 148 events in the standard treatment group; HR: 0.66; 95% CI: 0.51–0.85 and all-cause mortality (73 deaths vs. 107 deaths, respectively; HR: 0.67; 95% CI: 0.49–0.91. No difference in falls, orthostatic hypotension, or overall SAEs.

- NNT for 1° outcome=27 and NNT for all-cause mortality=41

**Limitations:** Does not apply to nursing home pts or those with dementia or advance

**Conclusions:** Intensive SBP is safe and effective for lowering CVD events and total mortality in adults ≥75 y

---

| INTERACT2 Anderson CS, et al., 2013 (191) 23713578 | **Aim:** To assess whether rapid lowering of elevated BP would improve the outcome in pts with ICH. | **Inclusion criteria:** Pts with spontaneous ICH within the previous 6 h with elevated SBP | **Design:** Intensive treatment to lower BP (with a target systolic level of <140 mm Hg within 1 h) vs. guideline-recommended treatment (with a target SBP <180 mm Hg) among pts with SBP between 150 and 220 mm using agents of the physician’s choosing. | **1° outcome:** Death or major disability (score of 3 to 6 on the modified Rankin scale) at 90 d. | **Summary:**
- In pts with ICH, intensive lowering of BP did not result in a significant reduction in the rate of death or severe disability.
- However, there may be improved functional outcomes with intensive lowering of BP.

**Pre-specified 2° outcome:** Ordinal analysis of the modified Rankin score.

**Key findings:**
- Among the 2,794 pts for whom the 1° outcome could be determined, 719 of 1,382 participants (52.0%) receiving
| ATACH-1 2010 (192) 19770736 | **Aim:** To determine the feasibility and acute (i.e., within 72 h) safety of 3 levels of SBP reduction in subjects with supratentorial ICH treated within 6 h after symptom onset.  
**Study type:** Phase I, dose-escalation, multicenter prospective study.  
**Study size:** 60 | **Inclusion criteria:** Pts with ICH with elevated SBP ≥170 mm Hg who presented to the ED within 6 h of symptom onset. | **Design:**  
- IV nicardipine to reduce SBP to a target of:  
  #1: 170–200 mm Hg in the first cohort of pts  
  #2: 140–170 mm Hg in the 2nd cohort  
  #3: 110–140 mm Hg in the third cohort.  
- Each subject was followed-up for 3 mo to preliminarily assess mortality and the clinical outcomes. A total of 18, 20, and 22 pts were enrolled in the respective 3 tiers of SBP treatment goals.  
**1° outcome:** Treatment feasibility (achieving and maintaining the SBP goals for 18–24 h)  
**2° outcomes:**  
#1: Neurologic deterioration within 24 h;  
#2: Serious adverse events within 72 h.  
**Key findings:**  
- Overall, 9 of 60 pts had treatment failures (all in the last tier). A total of 7 subjects with neurologic deterioration were observed: 1 (6%), 2 (10%), and 4 (18%) in tier 1, 2, and 3, respectively.  
- Serious adverse events were observed in 1 subject (5%) in tier 2 and in 3 subjects (14%) in tier 3. However, the safety stopping rule was not activated in any of the tiers.  
- 3 (17%), 2 (10%), and 5 (23%) subjects in tiers 1, 2, and 3, respectively, died within 3 mo  
**Summary:** Observed proportions of neurologic deterioration and serious adverse events were below the prespecified safety thresholds, and the 3-mo mortality rate was lower than expected in all SBP tiers. | intensive treatment, vs. 785 of 1,412 (55.6%) receiving guideline-recommended treatment, had a 1° outcome event; intensive treatment OR: 0.87; 95% CI: 0.75–1.01; p=0.06.  
- The ordinal analysis showed significantly lower modified Rankin scores with intensive treatment. OR for greater disability: 0.87; 95% CI: 0.77–1.00; p=0.04.  
- Mortality was 11.9% in the group receiving intensive treatment and 12.0% in the group receiving guideline-recommended treatment.  
- Nonfatal serious adverse events occurred in 23.3% and 23.6% of the pts in the 2 groups, respectively.  
- No clear relationship between outcome and time from onset of ICH to commencing treatment and no significant effect of intensive BP-lowering treatment on hematoma growth.  
- Of note, only 1 third of pts achieved the target SBP level within 1 h (half achieved the target by 6 h), and most (75%) presented with mild to moderate size (<20 mL) hematomas. |  

| INTERACT-1  | **Aim:** To assess the safety and efficiency of early intensive lowering of BP (target SBP)  
**Inclusion criteria:** Pts with supratentorial ICH | **Design:** Early intensive lowering of BP (target SBP)  
**1° outcome:** Proportional change in hematoma volume at 24 h.  
**Summary:** Early intensive BP-lowering treatment is clinically |  |
Anderson CS, et al., 2008 (193) (18396107)

| Study type: | Randomized pilot trial |
| Study size: | 404 |

acute spontaneous ICH diagnosed by CT within 6 h of onset, elevated SBP (150–220 mm Hg), and no definite indication or contraindication to treatment

140 mm Hg; n=203) vs. standard guideline-based management of BP (target SBP 180 mm Hg; n=201).

2° outcomes: Measurements of hematoma volume.

Safety and clinical outcomes: Assessed for up to 90 d.

Key findings:
- Mean hematoma volumes were smaller in the guideline group (12.7 mL, SD 11.6) than in the intensive group (14.2 mL, SD 14.5).
- From randomization to 1 h, mean SBP was 153 mm Hg in the intensive group and 167 mm Hg in the guideline group (difference 13.3 mm Hg (95% CI: 8.9–17.6) mm Hg; p<0.0001); from 1 h to 24 h, BP was 146 mm Hg in the intensive group and 157 mm Hg in the guideline group (10.8 mm Hg; 95% CI: 7.7–13.9 mm Hg; p<0.0001).
- Mean proportional hematoma growth was 36.3% in the guideline group and 13.7% in the intensive group (difference 22.6%; 95% CI: 0.6%–44.5%; p=0.04) at 24 h.
- After adjustment for initial hematoma volume and time from onset to CT, median hematoma growth differed between the groups with p=0.06; the absolute difference in volume between groups was 1.7 mL (95% CI: -0.5–3.9; p=0.13). RR of hematoma growth ≥33% or ≥12.5 mL was 36% lower (95% CI: 0%–59%; p=0.05) in the intensive group than in the guideline group. Adjusted RR: 8% (95% CI: -1.0%–17%; p=0.05).
- Intensive BP-lowering treatment did not alter the risks of adverse events or 2° clinical outcomes at 90 d.

feasible, well tolerated, and might reduce hematoma growth in ICH.

| Tsvigoulis G, et al., 2014 (194) 25239836 | To evaluate the safety and efficacy of intensive BP reduction in pts with acute-onset ICH | Pts with acute ICH randomized to either intensive or guideline BP-reduction protocols. | *Intensive early BP lowering after acute ICH onset compared with guideline-based treatment* | ● Death rates similar between pts randomized to intensive BP-lowering treatment and those receiving guideline BP-lowering treatment OR: 1.01; 95% CI: 0.83–1.23; p=0.914  
● Intensive BP-lowering treatment associated with strong trend towards lower 3-mo death or dependency vs. guideline treatment OR: 0.87; 95% CI: 0.76–1.01; p=0.062.  
● Intensive BP reduction was also associated with a greater attenuation of absolute hematoma growth at 24 h (standardized MD± standard error: -0.110 ± 0.053; p=0.038). | ● Intensive BP management in pts with acute ICH is safe.  
● Intensively treated ICH pts tended to have more favorable 3-mo functional outcome.  
● Intensive BP reduction associated with a greater attenuation of absolute hematoma growth at 24 h.  
● Starting antihypertensive treatment in the initial 5–10 d after ICH may have a different outcome from that seen after an ischemic stroke because of 2º edema formation and hemodynamic changes. |
| ATACH2 Qureshi AI, et al., 2016 27276234 | To determine the relative efficacy of intensive vs. standard antihypertensive treatment that was initiated within 4.5 H after symptom onset and continued for the next 24 H in patients with spontaneous supratentorial intracerebral hemorrhage | Pts with spontaneous ICH (volume, <60 cm3) and a Glasgow Coma Scale (GCS) score of 5 or more | *Intensive BP-lowering after acute ICH onset compared with guideline-based treatment* | ● Among 1,000 participants with a mean (±SD) systolic BP of 200.6±27.0 mm Hg at baseline, 500 were assigned to intensive treatment and 500 to standard treatment. Enrollment was stopped because of futility  
● Death or disability occurred in 38.7% of patients in the intensive-treatment group and 37.7% in the standard-treatment group. RR: 1.04; 95%CI: 0.85–1.27.  
● Serious adverse events occurring within 72 H after randomization were reported in 1.6% of the patients in the intensive-treatment group and 1.2% of those in the standard-treatment group.  
● Renal adverse events within 7 d after randomization were significantly higher in the intensive-treatment group than in the standard-treatment group. | Treatment of patients with spontaneous ICH to achieve a target systolic BP of 110 to 139 mm Hg did not result in a lower rate of death or disability compared to conventional reduction to a target of 140–179 mm Hg. Furthermore, there was more than twice the frequency of renal adverse events in the more intensively treated arm within a week of treatment initiation. |

**Safety endpoint:** Adverse events, minor and serious: p>0.05 for all | **Relevant 2° endpoint**  
• 2-wk NIHSS: p=0.46 and 2-wk Barthel Index: p=0.30  
• 2-wk BP: significantly lower in the continue arm (mean difference of -13 mm Hg in SBP and -8 mm Hg in DBP) p<0.0001  
• 6-month mortality: p=0.98; 6-month disability p<0.05  
**Study limitations**  
• Trial was terminated early because of slow recruitment, and consequently it was underpowered  
• Treatment was not homogeneous (different drugs, no specific BP target)  
• No differences when analysis restricted to patients with ischemic stroke  
**Summary/conclusions**  
• Early reinitiation of antihypertensive medications was safe but ineffective to prevent death or dependency  
• Early reinitiation of antihypertensives was associated with better BP control at 2 wk |

| CATIS | Evaluate whether immediate blood pressure reduction in patients with acute ischemic stroke would reduce death and major disability at 14 d or hospital discharge | **Inclusion criteria:**  
- Age >22 y  
- Acute ischemic stroke within previous 24 h  
**Exclusion criteria:**  
- Impaired level of consciousness  
- Hypertensive emergency  
- BP >220/120  
- Atrial fibrillation  
- Intravenous alteplase | **Intervention:** Antihypertensive medication to maintain BP <140/90 for the first wk (n=2038) | **1° endpoint:** Death or major disability (mRS 3–6) at 14 d: OR: 1.0 (95% CI: 0.88–1.14; p=0.98) | **Relevant 2° endpoint:**  
- Death or major disability (mRS 3–5) at 90 d: OR: 0.99 (95% CI: 0.86–1.15; p=0.93)  
- Lower blood pressure at 14 d (mean difference of -8.6 mm Hg in SBP and -3.9 mm Hg in DBP; p<0.001) and at 90 d (mean difference of -2.9 mm Hg in SBP and -1.4 mm Hg in DBP; p<0.001) in the active arm |

**Safety endpoint:**  
- Vascular disease events p=0.28  
- Recurrent stroke p=0.07

**Study type:** RCT  
**Size:** 4071

| Wang H, et al., 2014 (195) | To assess the effects of early BP lowering on early and long-term outcomes after acute stroke. | **Inclusion criteria:**  
- Prospective RCTs of pts ≥18 y with acute ischemic or hemorrhagic stroke; intervention compared with placebo was initiated within 7 d of stroke onset; intervention aimed to lower BP or intervention achieved BP reduction; 1 or more functional outcomes reported, such as death or dependency. | Early BP lowering after acute stroke onset compared with placebo | **1° outcomes:** Early (within 30 d) and long-term (from 3–12 mo). | **Summary:** Results do not support early BP lowering after acute stroke. Early BP lowering may be associated with greater risk of death within 30 d after acute stroke. |

**Key findings:**  
- Early BP lowering after acute stroke onset associated with more death within 30 d compared with placebo RR: 1.34; 95% CI: 1.02–1.74; p=0.03.  
- Early BP lowering after acute stroke onset not associated with early neurological deterioration, early death within 7 d, long-term death, early and long-term dependency, early and long-term combination of death or dependency, long-term stroke recurrence, long-term MI and long-term CVE. | **Study type:** Systematic review and meta-analysis of RCTs  
**Study size:** 17 trials (n=13,236 pts) | **Study limitations**  
Antihypertensive regimen was not standardized  
**Summary/conclusions**  
- Early treatment of hypertension was safe but ineffective to prevent death or dependency  
- Early initiation of anti-hypertensives was associated with better BP control at 2 wk |

|                                    | **Key findings:**  
|                                    | • At 24 h after randomization #1: Oral ACEIs reduced SBP MD: -8 mm Hg (95% CI: -17–1) and DBP MD: -3 mm Hg (95% CI: -9–2), sublingual ACEIs reduced SBP MD: -12.00 mm Hg (95% CI: -26–2) and DBP MD: -2 (95% CI: -10–6).  
• Oral angiotensin receptor antagonists reduced SBP MD: -1 mm Hg (95% CI: -3–2) and DBP MD: -1 mm Hg (95% CI: -3–1).  
• Oral BBs reduced SBP MD: -14 mm Hg (95% CI: -27–-1) and DBP MD: -1 mm Hg (95% CI: -9–7), IV BBs reduced SBP MD: -5 mm Hg (95% CI: -18–8) and DBP MD: -5 mm Hg (95% CI: -13–3).  
• Oral CCBs reduced SBP MD: -13 mm Hg (95% CI: -.43–17) and DBP MD: -6 mm Hg (95% CI: -14–2). IV CCBs reduced SBP MD: -32 mm Hg (95% CI: -.65–1) and DBP MD: -13 (95% CI: -.31–6).  
• Nitric oxide donors reduced SBP MD: -12 mm Hg (95% CI: -19–5) and DBP MD: -3 (95% CI: -4–2). |
|                                    | **Summary:**  
|                                    | • No current evidence showing that lowering BP during the acute phase of stroke improves functional outcome.  
• It seems reasonable to withhold BP-lowering drugs until pts are medically and neurologically stable, after which drugs can then be reintroduced.  
• CCBs, ACEI, angiotensin receptor antagonists, BBs and nitric oxide donors each lower BP in acute stroke while phenylephrine appears to increase BP. |

**Aim:** To assess the clinical effectiveness of altering BP in pts with acute stroke, and the effect of different vasoactive drugs on BP in acute stroke. Update of previously published Cochrane reviews (1997, 2001, and 2008).

**Comparator:** Placebo (n=100)

- Nimodipine as IV infusion of 2 mg/h for 5 d followed by oral dose of 120 mg daily for a total treatment period of 21 d (n=94)
- A significant correlation between DBP reduction and worsening of the neurological score was found for the high-dose group (beta=0.49; p=0.048).
- Pts with a DBP reduction of ≥20% in the high-dose group had a significantly increased adjusted OR for death or dependency (n/N=25/26, OR: 10.16; 95% CI: 1.02–101.74) and death alone (n/N=9/26, OR: 4.336; 95% CI: 1.131–16.619) vs. all placebo pts (n/N=62/92 and 14/92, respectively). No correlation between SBP change and outcome.

### Aim
To determine the association of BP and antihypertensive therapy with clinical outcomes after thrombolysis for acute ischemic stroke.

### Study type:
Retrospective analysis of prospectively maintained thrombolysis registry.

### Inclusion criteria:
- Pts with acute ischemic stroke treated with IV rtPA
- BP values were recorded at baseline, 2 h, and 24 h after thrombolysis.

### Categories:
By history of HTN and antihypertensive therapy within 7 d after thrombolysis:
- Group 1, HTN treated with antihypertensives (n=5,612)

### Outcomes:
Symptomatic (National Institutes of Health Stroke Scale score deterioration ≥4) ICH Type 2, mortality, and independence at (modified Rankin Score 0 to 2) 3 mo.

### Key findings:
- High SBP 2–24 h after thrombolysis as a continuous variable was associated with worse outcome (p=0.001) and as a categorical variable had a linear association with symptomatic hemorrhage and a U-shaped association with mortality and independence with SBP 141–150 mm Hg associated with most favorable outcomes.
- No difference in symptomatic hemorrhage OR: 1.09 (95% CI: 0.83–1.51; p=0.58) and independence OR: 1.03 (95% CI: 0.93–1.10; p=0.80) but lower mortality OR: 0.82 (95% CI: 0.68–0.98).

### Summary:
- Strong association of high SBP after thrombolysis with poor outcome.
- Higher BP during initial 24 h were associated with greater risk of ICH in a linear fashion.
- U-shaped relation found between BP during initial 24 h and death or dependency at 3 mo, with best outcomes associated with SBP of 141–150 mm Hg.

---

**Size:** 26 trials involving 17,011 pts (8,497 pts were assigned active therapy and 8,514 pts received placebo/control). Not all trials contributed to each outcome.

- Phenylephrine, nonsignificantly increased SBP MD: 21 mm Hg (95% CI: -13–55) and DBP MD: 1 mm Hg (95% CI: -15–16).
- BP lowering did not reduce death or dependency either by drug class OR: 0.98 (95% CI: 0.92–1.05), stroke type OR: 0.98 (95% CI: 0.92–1.05) or time to treatment OR: 0.98 (95% CI: 0.92–1.05).
- Treatment within 6 h of stroke appeared effective in reducing death or dependency OR: 0.86 (95% CI: 0.76–0.99) but not death OR: 0.70 (95% CI: 0.38–1.26) by trial end.
- While death or dependency did not differ between pts who continued pre-stroke antihypertensive treatment vs. those who stopped it temporarily (worse outcome with continuing treatment OR: 1.06; 95% CI: 0.91–1.24), disability scores at the end of the trial were worse in pts randomized to continue treatment (Barthel Index MD: -3.2 (95% CI: -5.8–-0.6).

---

### SITS-ISTR
Ahmed N, et al., 2009 (199)

**Aim:**
To determine the association of BP and antihypertensive therapy with clinical outcomes after thrombolysis for acute ischemic stroke.

**Study type:**
Retrospective analysis of prospectively maintained thrombolysis registry.

**Inclusion criteria:**
- Pts with acute ischemic stroke treated with IV rtPA
- BP values were recorded at baseline, 2 h, and 24 h after thrombolysis.

**Categories:**
By history of HTN and antihypertensive therapy within 7 d after thrombolysis:
- Group 1, HTN treated with antihypertensives (n=5,612)

**1° outcomes:**
Symptomatic (National Institutes of Health Stroke Scale score deterioration ≥4) ICH Type 2, mortality, and independence at (modified Rankin Score 0 to 2) 3 mo.

**Key findings:**
- High SBP 2–24 h after thrombolysis as a continuous variable was associated with worse outcome (p=0.001) and as a categorical variable had a linear association with symptomatic hemorrhage and a U-shaped association with mortality and independence with SBP 141–150 mm Hg associated with most favorable outcomes.
- No difference in symptomatic hemorrhage OR: 1.09 (95% CI: 0.83–1.51; p=0.58) and independence OR: 1.03 (95% CI: 0.93–1.10; p=0.80) but lower mortality OR: 0.82 (95% CI: 0.68–0.98).
### ACCESS

**Schrader J, et al., 2003 (200)**

12817109

**Aim:** To assess safety of modest BP reduction by candesartan in early treatment of stroke; and provide an estimate of the number of cases required to perform a larger phase III efficacy study.

**Study type:** Prospective, double-blind, RCT; multicenter phase II study.

**Size:** 342 pts

**Inclusion criteria:**
- Motor deficit, a cerebral CT scan excluding ICH, and necessity to treat HTN per prevailing recommendation
- Exclusion criteria:
  - >85 y, disorders in consciousness preventing acquisition of consent, occlusion or >70% stenosis of the internal carotid artery, malignant HTN, manifest cardiac failure, high-grade aortic or mitral stenosis, UA pectoris, or contraindications against candesartan.

**Design:**
- 4 mg candesartan daily or placebo on d 1. On d 2, dosage was increased to 8 or 16 mg candesartan or placebo if BP >60 mm Hg SBP or 100 mm Hg DBP. Treatment was targeted to a 10%–15% BP reduction within 24 h.

**1º outcome:** Trial was stopped prematurely when 342 pts (339 valid) had been randomized because of an imbalance in endpoints.

**Key findings:** Cumulative 12 mo mortality and the number of vascular events differed significantly in favor of the candesartan cilexetil group (OR: 0.475; 95% CI: 0.252–0.895).

**Summary:** Early antihypertensive therapy with candesartan might be a safe therapeutic option in acute stroke, but study sample size very small.

### SCAST

**Sandset EC, et al., 2011 (201)**

21316752

**Aim:** To examine whether careful BP-lowering treatment with the candesartan is

**Inclusion criteria:**
- Pts >18 y with acute stroke (ischemic or hemorrhagic) and SBP of ≥140 mm Hg were randomized to candesartan (n=1,017) or placebo (1,012) (1:1) for 7 d, with doses

**Design:**

**1º effect variables:** Composite of vascular death, MI, or stroke during the first 6 mo; and functional outcome at 6 mo, as measured by the modified Rankin Scale.

**Relevant 2º endpoint:**
- Similar effects for all prespecified 2º endpoints.
- During follow-up, 9 (1%) pts on candesartan and 5 (<1%) on
**Study**

**Study type:** Double-blind RCT  
**Study size:** 2,029 pts

**Key findings:**  
- BPs significantly lower in pts allocated candesartan vs. placebo (mean 147/82 mm Hg [SD 23/14] in the candesartan group on d 7 vs. 152/84 mm Hg [22/14] in the placebo group; p<0.0001).  
- Risk of the composite vascular endpoint did not differ between treatment groups (candesartan, 120 events, vs. placebo, 111 events; adjusted HR: 1.09; 95% CI: 0.84–1.41; p=0.52.  
- Analysis of functional outcome suggested a higher risk of poor outcome in the candesartan group (adjusted OR: 1.17; 95% CI: 1.00–1.38; p=0.048.

**Summary:** Careful BP-lowering treatment with candesartan was not beneficial in pts with acute stroke and raised BP. Indeed, there was the suggestion of a harmful effect.

---

**CATIS**

**Aim:** To evaluate whether immediate BP reduction in pts with acute ischemic stroke would reduce death and major disability at 14 d or hospital discharge.  
**Study type:** Single-blind, blinded end-points RCT.  
**Study size:** 4,071 pts

**Inclusion criteria:** Pts with nonthrombolysed ischemic stroke within 48 h of onset and elevated SBP

**Design:** Pts (n=2,038) randomized to antihypertensive treatment (aimed at lowering SBP by 10% to 25% within first 24 h, achieving BP <140/90 mm Hg within 7 d, and maintaining this level during hospitalization) vs. to discontinue all antihypertensive medications (control) during hospitalization (n=2,033).

**1° outcome:** Combination of death and major disability (modified Rankin Scale score ≥3) at 14 d or hospital discharge.

**Key findings:**  
- Mean SBP was reduced from 166.7 mm Hg to 144.7 mm Hg (-12.7%) within 24 h in the antihypertensive treatment group and from 165.6 mm Hg to 152.9 mm Hg (-7.2%) in the control group within 24 h after randomization (difference, -5.5% (95% CI: -4.9–-6.1%); absolute difference, -9.1 mm Hg (95% CI: -10.2–-8.1), p<0.001).  
- 1° outcome did not differ between treatment groups (OR: 1.00; 95% CI: 0.88–1.14; p=0.98) at 14 d or hospital discharge.  
- BP at 14 d and 90 d: significantly lower in the active arm (mean difference of -2.9 mm Hg in systolic BP and -1.4 mm Hg in diastolic BP)

**Relevant 2° endpoint:** Death and major disability at 3-mo posttreatment follow-up did not differ between treatment groups (500 events [antihypertensive treatment] vs. 502 events [control]; OR: 0.99; 95% CI: 0.86–1.15; p=0.93).

**Summary:** Among pts with acute ischemic stroke, BP reduction with antihypertensive medications, vs. absence of hypertensive medication, did not reduce the likelihood of death and major disability at 14 d or hospital discharge.  
- Early initiation of antihypertensives was associated with better BP control at 2 wk
**COSSACS**
Robinson TG, et al., 2010 (203)

Aim: To assess the efficacy and safety of continuing or stopping pre-existing antihypertensive drugs in pts who recently had a stroke.

**Inclusion criteria:** Pts >18 y taking antihypertensive drugs enrolled within 48 h of stroke and last dose of antihypertensive drug.

**Design:** Continue (n=379) or stop (n=384) pre-existing antihypertensive drugs for 2 wk.

**1° outcome:** Death or dependency at 2 wk.

**Key findings:**
- 72 of 379 pts in the continue group and 82 of 384 pts in the stop group reached the 1° endpoint RR: 0.86; 95% CI: 0.65–1.14; p=0.3.
- Difference in SBP at 2 wk between the continue group and the stop group was 13 mm Hg (95% CI: 10–17) and the difference in DBP was 8 mm Hg (6–10; difference between groups; p<0.0001).
- No substantial differences were observed between groups in rates of serious adverse events, 6-mo mortality, or major CV events.

**Summary:**
- Continuation of antihypertensive drugs did not reduce 2-wk death or dependency, CV event rate, or mortality at 6 mo
- Early reinitiation of antihypertensives was associated with better BP control at 2 wk
- Lower BP levels in those who continued antihypertensive treatment after acute mild stroke were not associated with an increase in adverse events.
- Of note, COSSACS was likely underpowered due to early termination of the trial.

---

**CHHIPS**
Potter JF, et al., 2009 (204)

Aim: To assess feasibility, safety, and effects of 2 regimens for lowering BP in pts who with acute stroke.

**Inclusion criteria:** Pts with cerebral infarction or cerebral hemorrhage who were hypertensive SBP >160 mm Hg.

**Design:**
- Within 36 h of symptom onset:
  - #1: Oral labetalol, lisinopril vs. placebo if they were nondysphagic;
  - #2: IV labetalol, sublingual lisinopril, or placebo if they had dysphagia.
  - Labetalol (n=58), lisinopril (n=58), or placebo (n=63).
  - Doses were titrated up if target BP was not reached.

**1° outcome:** Death or dependency at 2 wk.

**Key findings:**
- 1° outcome occurred in 61% (69) of the active vs. 59% (35) of the placebo group (RR: 1.03; 95% CI: 0.80–1.33; p=0.82)
- No evidence of early neurological deterioration with active treatment (RR: 1.22; 95% CI: 0.33–4.54; p=0.76) despite greater drop in SBP within the first 24 h in this group vs. placebo (21 [17–25] mm Hg vs. 11 [5–17] mm Hg; p=0.004).
- No rise in serious adverse events with active treatment (RR: 0.91; 95% CI: 0.69–1.12; p=0.50) but 3-mo mortality was halved (9.7% vs. 20.3%; HR: 0.40; 95% CI: 0.2–1.0; p=0.05).

**Summary:**
- Labetalol and lisinopril are effective antihypertensive drugs in acute stroke that do not raise risk of serious adverse events.
- Early lowering of BP with lisinopril and labetalol after acute stroke may be a promising approach to lower mortality and disability.
- However, pilot nature and very small sample size limit generalizability.

---

**Bath PM, et al., 2015 (205)**

Aim: To assess outcomes after stroke in pts given transdermal glyceryl trinitrate.

**Inclusion criteria:** Pts admitted to hospital with an acute ischemic stroke

**Design:**
- 7 d of transdermal glyceryl trinitrate (5 mg

**1° outcome:** Function, assessed with the modified Rankin Scale at 90 d

**Summary:**
- In pts with acute stroke and high BP transdermal glyceryl trinitrate...
### Key Findings
- Mean BP was 167 (SD: 19) mm Hg/90 (13) mm Hg at baseline (median 26 h (16–37) after stroke onset), and was significantly reduced on d 1 in 2,000 pts allocated to glyceryl trinitrate vs. 2,011 controls (difference -7.0 (95% CI: -8.5– -5.6) mm Hg/-3.5 [-4.4– -2.6] mm Hg; both p<0.0001), and on d 7 in 1,053 pts allocated to continue antihypertensive drugs compared with 1,044 pts randomized to stop them (difference: -9·5 (95% CI: -11.8– -7.2) mm Hg/-5.0 [-6.4– -3.7] mm Hg; both p<0.0001).
- D-90 functional outcome did not differ in either treatment comparison-glyceryl trinitrate vs. no glyceryl trinitrate (OR: 1.01; 95% CI 0.91–1.13; p=0·83), and with continue vs. stop antihypertensive drugs (OR: 1.05; 95% CI: 0.90–1.22; p=0.55).
- Continuing prestroke antihypertensive drugs in acute stroke pts in the first few d did not confer benefit.

### Summary
- Observed proportions of neurologic deterioration and serious adverse events were below the prespecified safety thresholds, and the 3-mo mortality rate was lower than expected in all SBP tiers.
- Results formed the basis of an ongoing larger randomized trial (ATACH-2) addressing the efficacy of SBP reduction in pts with ICH.
| INTERACT-1 | **Aim:** To assess the safety and efficiency of this treatment, as a run-in phase to a larger trial.  
**Study type:** Randomized pilot trial  
**Study size:** 404 | **Inclusion criteria:** Pts with acute spontaneous ICH diagnosed by CT within 6 h of onset, elevated SBP (150–220 mm Hg), and no definite indication or contraindication to treatment | **Design:** Early intensive lowering of BP (target SBP 140 mm Hg; n=203) vs. standard guideline-based management of BP (target SBP 180 mm Hg; n=201).  
**1° outcome:** Proportional change in hematoma volume at 24 h.  
**2° outcomes:** Measurements of hematoma volume.  
**Safety and clinical outcomes:** Assessed for up to 90 d.  
**Key findings:**  
- Mean hematoma volumes were smaller in the guideline group (12.7 mL, SD 11.6) than in the intensive group (14.2 mL, SD 14.5).  
- From randomization to 1 h, mean SBP was 153 mm Hg in the intensive group and 167 mm Hg in the guideline group (difference 13.3 mm Hg (95% CI: 8.9–17.6) mm Hg; p<0.0001); from 1 h to 24 h, BP was 146 mm Hg in the intensive group and 157 mm Hg in the guideline group (10.8 mm Hg; 95% CI: 7.7–13.9 mm Hg; p<0.0001).  
- Mean proportional hematoma growth was 36.3% in the guideline group and 13.7% in the intensive group (difference 22.6%; 95% CI: 0.6%–44.5%; p=0.04) at 24 h.  
- After adjustment for initial hematoma volume and time from onset to CT, median hematoma growth differed between the groups with p=0.06; the absolute difference in volume between groups was 1.7 mL (95% CI: -0.5–3.9; p=0.13). RR of hematoma growth ≥33% or ≥12.5 mL was 36% lower (95% CI: 0%–59%; p=0.05) in the intensive group than in the guideline group. Adjusted RR: 8% (95% CI: -1.0%–17%; p=0.05).  
- Intensive BP-lowering treatment did not alter the risks of adverse events or 2° clinical outcomes at 90 d.  
**Summary:** Early intensive BP-lowering treatment is clinically feasible, well tolerated, and appears to reduce hematoma growth in ICH. | Hack W, et al., 2008 (206)  
**Aim:** To assess the efficacy and  
**Inclusion criteria:** Pts 18–80 y, who had  
**Design:**  
**1° outcome:** Disability at 90 d, dichotomized as a favorable outcome (a score of 0 or 1 on Summary:** Compared with placebo, IV alteplase administered between 3
| 18815396 | safety of alteplase administered between 3 and 4.5 h after the onset of a stroke.  
**Study type:** RCT  
**Study size:** 821 pts | received a clinical diagnosis of acute ischemic stroke, and were able to receive the study drug within 3–4 h after the onset of symptoms.  
**Exclusion criteria:** SBP >185 mm Hg or DBP >110 mm Hg or aggressive treatment (IV medication) necessary to reduce BP to these limits | ● Eligible pts were randomly assigned 1:1 to receive 0.9 mg of alteplase per kg, administered IV (with an upper limit of 90 mg), or placebo.  
● 418 pts were assigned to receive alteplase and 403 pts were assigned to receive placebo | the modified Rankin scale, which has a range of 0–6, with 0 indicating no symptoms at all and 6 indicating death) or an unfavorable outcome (a score of 2–6 on the modified Rankin scale).  
**2º outcome:** global outcome analysis of 4 neurologic and disability scores combined.  
**Safety outcomes:** death, symptomatic intracranial hemorrhage, and other serious adverse events.  
**Key findings:**  
● More pts had a favorable outcome with alteplase than with placebo (52.4% vs. 45.2%; OR: 1.34; 95% CI: 1.02–1.76; p=0.04).  
● Incidence of ICH was higher with alteplase than with placebo (for any ICH, 27.0% vs. 17.6%; p=0.001; for symptomatic intracranial hemorrhage, 2.4% vs. 0.2%; p=0.008).  
● Mortality did not differ significantly between the alteplase and placebo groups (7.7% and 8.4%, respectively; p=0.68).  
● No significant difference in the rate of other serious adverse events. |  
| NINDS rt-PA Stroke Study Group, 1995 (207)  
7477192 | **Aim:** To assess the difference in clinical efficacy between IV t-PA and placebo among pts with an acute ischemic stroke  
**Study type:** Double-blind RCT | **Inclusion criteria:** Pts with an ischemic stroke with a clearly defined time of onset (<3 h), a deficit measurable on the NIH stroke scale, and a base-line CT scan of the brain that showed no evidence of ICH.  
**Exclusion criteria:** | **Design:** RCT with acute ischemic stroke pts randomized to t-PA vs. placebo  
**1º outcome:** Clinical outcome at 3 mo, according to scores on the Barthel index, modified Rankin scale, Glasgow outcome scale, and NIH stroke scale:  
**Key findings:**  
● As compared with pts given placebo, pts treated with t-PA were at least 30% more likely to have minimal or no disability at 3 mo on the assessment scales.  
● Symptomatic ICH within 36 h after the onset of stroke occurred in 6.4% of pts given and 4.5 h after the onset of symptoms significantly improved clinical outcomes in pts with acute ischemic stroke; alteplase was more frequently associated with symptomatic ICH. |

<th>Relevant 2° Endpoint (if any); Study Limitations; Adverse Events; Summary</th>
</tr>
</thead>
</table>
| Post-stroke Antihypertensive Treatment Study (PATS) 1995 (208) 8575241 | **Aim:** To assess whether lowering BP prevents the recurrence of stroke in Chinese pts with history of cerebrovascular disease | **Inclusion criteria:** Pts with history of stroke or TIA  
**Exclusion criteria:** N/A | **Intervention:** Indapamide 2.5 mg daily (n=2,840 pts)  
**Comparator:** Placebo (n=2,825 pts) | **1° outcome:** Recurrence of fatal or nonfatal stroke.  
**Key findings:** Average SBP/DBP at randomization was 153.8/92.8 mm Hg. At median follow-up (2 y), BP was 6.8/3.3 mm Hg lower in pts on active treatment. 143 pts on indapamide vs. 219 pts on placebo had recurrent strokes (HR: 0.69; 95% CI: 0.54–0.89; p<0.001).  
**2° outcome:**  
- Major fatal and nonfatal CV events: In addition, 199 pts on indapamide and 258 pts on placebo had a CV event (HR: 0.75; 95% CI: 0.89–0.62; p=0.002).  
- 2,825 pts received a placebo and 2,840 pts received.  
**Summary:** For pts with a history of stroke or TIA, BP reduction of 5/2 mm Hg with 2.5 mg of indapamide lowered the first incidence of fatal and nonfatal stroke by 29%, with 3-y absolute benefit of 29 events per 1,000 pts. |
| PROGRESS 2001 (209) 11589932 | **Aim:** To determine effects of a BP-lowering regimen in hypertensive and nonhypertensive pts with a history of stroke or TIA.  
**Study type:** Double-blind, placebo-controlled trial | **Inclusion criteria:** Pts with history of stroke (evidence of an acute disturbance of focal neurological function with symptoms lasting more than 24 h and | **Intervention:** Active treatment comprised a flexible regimen based on the ACEI perindopril (4 mg daily), with addition of diuretic indapamide at discretion of treating physicians (n=3,051)  
**Comparator:** Placebo (n=3,054) | **1° outcome:** Total stroke (fatal or nonfatal)  
**Key findings:**  
- Over 4 y of follow-up, active treatment reduced BP by 9/4 mm Hg. 307 (10%) pts assigned active treatment suffered a stroke, vs. 420 (14%) assigned placebo (RR reduction: 28% [95% CI: 17, 38], p<0.0001).  
- Combination therapy with perindopril plus indapamide reduced BP by 12/5 mm Hg and stroke risk by 43% (95% CI: 30–54%). Single-drug therapy reduced  
**Relevant 2° endpoint:** Active treatment also reduced the risk of total major vascular events (26% [16–34]). There were similar reductions in the risk of stroke in hypertensive and nonhypertensive subgroups (all p<0.01).  
**Summary:** This BP-lowering regimen reduced the risk of stroke among both hypertensive and nonhypertensive pts with a history of stroke or TIA. Combination therapy with perindopril and indapamide produced larger BP |
thought to be due to ICH or ischemia) or TIA within the previous 5 y.

**Exclusion criteria:** N/A

- Pts clinically stable for at least 2 wk after their most recent vascular event before entry to the study.

BP by 5/3 mm Hg and produced no discernable reduction in the risk of stroke.

- This trial showed the benefits of BP lowering in both hypertensive pts. However, based on older definitions, presence of baseline HTN in the trial was defined as ≥160/90 mm Hg.

### MOSES

**Schrader J, et al., 2005 (210) 15879332**

**Aim:** To assess among hypertensive stroke pts, whether for the same level of BP control, eprosartan would be more effective than nitrendipine in reducing cerebrovascular and CV morbidity and mortality.

**Study type:** PROBE design

**Size:** 1,405

<table>
<thead>
<tr>
<th>Inclusion criteria</th>
<th>Intervention: Eprosartan 600 mg (n=681)</th>
<th><strong>1° endpoint:</strong> Composite of total mortality and all CV and cerebrovascular events, including all recurrent events.</th>
</tr>
</thead>
<tbody>
<tr>
<td>High-risk hypertensives with cerebral event during the last 24 mo (proven by cerebral CT scan or nuclear magnetic resonance)</td>
<td>Comparator: Nitrendipine 10 mg (n=671)</td>
<td><strong>Key findings:</strong> BP reduced to comparable extent without significant differences between 2 groups during study period (150.7/84 mm Hg vs. 152.0/87.2 mm Hg with eprosartan and nitrendipine therapy to 137.5/80.8 mm Hg and 136.0/80.2 mm Hg, respectively). 75.5% reached values &lt;140/90 mm Hg with eprosartan regimen and 77.7% with nitrendipine. During follow-up, 461 1° events occurred: 206 eprosartan and 255 nitrendipine (IDR: 0.79; 95% CI: 0.66–0.96; p=0.014).</td>
</tr>
</tbody>
</table>

**Relevant 2° endpoint:** CV events were: 77 eprosartan and 101 nitrendipine (IDR: 0.75; 95% CI: 0.55–1.02; p=0.06); cerebrovascular events: 102 eprosartan and 134 nitrendipine (IDR: 0.75; 95% CI: 0.58–0.97; p=0.03).

**Summary:**

- The combined 1° endpoint was significantly lower in the eprosartan group.
- However, it was a reduction in TIAs that accounted for most of the benefit in cerebrovascular events, with no significant difference in ischemic strokes.
- Also a more traditional analysis of time to first cerebrovascular event did not show a benefit of eprosartan.
PROFESS
Yusuf S, et al., 2008 (211) 18753639

**Aim:** To evaluate the effects of therapy with an ARB, telmisartan, initiated early after a stroke

**Study type:** Double-blind RCT

**Size:** 20,332 pts

**Inclusion criteria:** Pts ≥55 y with an ischemic stroke <90 d before randomization

**Exclusion criteria:** 1° hemorrhagic stroke, severe disability after the qualifying stroke

**Intervention:** Telmisartan 80 mg daily (n=10,146)

**Comparator:** Placebo (n=10,186)

**1° endpoint:** Recurrent stroke

**Key findings:** During mean follow-up of 2.5 y, mean BP was 3.8/2.0 mm Hg lower in telmisartan group vs. placebo group. 880 pts (8.7%) in telmisartan group vs. 934 pts (9.2%) in placebo group had a subsequent stroke (HR: 0.95; 95% CI: 0.86–1.04; p=0.23).

**Relevant 2° endpoint:** Major CV events (death from CV causes, recurrent stroke, MI, or new or worsening HF) occurred in 1,367 pts (13.5%) in telmisartan group vs. 1,463 pts (14.4%) in placebo group (HR: 0.94; 95% CI: 0.87–1.01; p=0.11).

**Summary:**
- Therapy with telmisartan initiated soon after ischemic stroke and continued for 2.5 y did not significantly lower Rate of recurrent stroke, or major CV events.
- Impact of treatment with telmisartan may have been affected by the high rate of discontinuation of treatment medication because of hypotensive symptoms, syncope, diarrhea, and nausea experienced in the telmisartan arm and the more aggressive treatment with other standard antihypertensive therapies in the placebo arm. Thus, adverse side effects from treatment medications may affect quality of life and thus medication adherence after stroke.

SPS-3
Benavente OR, et al., 2013 (212) 23726159

**Aim:** To investigate effects of different BP targets on rate of recurrent stroke in pts

**Inclusion criteria:** Pts with recent, MRI-defined symptomatic

**Intervention:** SBP target of 130–149 mm Hg (n=1,519)

**1° outcome:** All stroke (including ischemic strokes and intracranial hemorrhages).

**Key findings:**
- No difference between target groups in disabling or fatal stroke 0.81, (95% CI: 0.53–1.23; p=0.32) or composite outcome of MI or vascular death 0.84 (95% CI: 0.68–1.04; p=0.32). However,
Study type: Randomized open-label trial  
**Size:** 3,020 pts  

<table>
<thead>
<tr>
<th>Inclusion criteria</th>
<th>Exclusion criteria</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pts with cortical strokes, cardioembolic disease, or carotid stenosis were excluded.</td>
<td>Pts with recent lacunar stroke.</td>
</tr>
</tbody>
</table>

**Comparator:** SBP target of <130 mm Hg (n=1,501)  
- After 1 y, mean SBP was 138 mm Hg (95% CI: 137–139) in the higher-target group and 127 mm Hg (95% CI: 126–128) in the lower-target group.
- Recurrent stroke was observed in 152 pts assigned to higher-target group (2.8% per y) vs. 125 assigned to the lower-target group (2.3% per y; HR: 0.81; 95% CI: 0.64–1.03).  
  - Hemorrhagic stroke occurred in 16 pts assigned to the higher-target group (0.29% per y) vs. 6 assigned to the lower-target group (0.11% per y; HR: 0.37 (95% CI: 0.15–0.95). Serious complications of hypotension were observed in 15 pts assigned to the higher-target group (0.26% per y) and 23 assigned to the lower-target group (0.40% per y; HR: 1.53; 95% CI: 0.80–2.93).

### Study by Liu L, et al., 2009 (215) 19798097

**Aim:** To examine role of BP reduction using antihypertensive agents to prevent recurrent stroke.

**Study type:** Systematic review and meta-analysis

**Size:** 10 RCTs

**Inclusion criteria:** Pts with a history of ischemic stroke, TIA, or ICH
Followed up 2 to 5 y.

**Exclusion criteria:** N/A

**1° outcome:** Recurrent stroke

**Key findings:** Antihypertensive drugs associated with significant reduction in recurrent strokes (RR: 0.78; 95% CI: 0.68–0.90).
Impact of antihypertensive treatment after ischemic stroke was similar in a restricted group of subjects with HTN and when all subjects, including those with and without HTN, were included.
Pooled OR: 0.63 (95% CI: 0.54–0.73; p<0.0001) for trials involving diuretics as a component of therapy and 0.93 (95% CI: 0.87–1.01; p=0.086) for trials in which treatment included renin system inhibitors (p<0.0001 for heterogeneity).

**Summary:** BP lowering agents reduced the occurrence of subsequent stroke and CV events. Rate of MI and all-cause mortality was unchanged.

### Study by Lee M, et al., 2012 (216) 21796663

**Aim:** To compare impact of achieving tight vs. usual SBP control on stroke prevention

**Study size:** 11 studies with 42,572 pts and 794 stroke events.

**Inclusion criteria:**
(1) Achieved SBP<130 mm Hg in an active treatment group and SBP 130 to 39 mm Hg in a comparator group by trial; (2) trial duration at least 6 mo; (3) total pts and number of stroke events reported separately for active treatment and comparator groups.

**Exclusion criteria:**
(1) Nonrandomized trials; (2) trials in which either the

**1° outcome:** Association of future stroke risk and achieved level of different SBP (intensive vs. usual)

**Key findings:**
- Final SBPs, weighted for trial size, were a mean of 126.5 mm Hg in the intensive treatment group and 132.6 mm Hg in the conventional arms (mean SBP reduction, 6.1 mm Hg).
- In subgroup analyses, those with established (symptomatic) CVD at entry did not experience stroke risk reduction with tight control (0.92; 95% CI: 0.83–1.03).

**Summary:** Achieving an SBP <130 mm Hg vs. 130–139 mm Hg appears to provide additional stroke protection only among pts with risk factors but no established CVD.
Lee M, et al., 2012 (217) 22052520

**Aim:** To evaluate whether use of ACEIs or ARBs reduces future vascular events in persons with prior stroke.

**Size:** 8 RCTs with 29,667 pts

**Inclusion criteria:**
1. RCT design
2. pts had a history of stroke or TIA
3. active treatment consisted of ACEIs or ARBs
4. follow-up duration at least 6 mo
5. total pts and number of future major vascular events and/or recurrent stroke were reported separately for active treatment and comparator groups.

**Exclusion criteria:**
1. mandatory ACEI or ARB use in control groups
2. study purpose was to examine efficacy of ACEIs or ARBs in pts with acute stroke

**1° outcome:** Major vascular event (nonfatal stroke, nonfatal MI, or death from CV causes) or stroke (ischemic or hemorrhagic)

**Key findings:**
- Use of ACEIs or ARBs in persons with prior stroke was associated with lower risks of future major vascular events RR: 0.91 (95% CI: 0.87–0.97; p=0.001); NNT=71 and recurrent stroke RR: 0.93 (95% CI: 0.86–0.99; p=0.03); NNT=143.

**Summary:**
- Treatment with an ACEI or ARB has a clear but rather modest effect on reducing vascular risk in persons with prior stroke.

Arima H, et al., 2006 (218) 16685221

**Aims:**
1. To investigate the effects of randomized treatment on recurrent stroke by baseline BP levels
2. To investigate association

**Inclusion criteria:**
- Pts with history of cerebrovascular event (stroke or TIA) within the previous 5 y

**Groups:**
- Defined by baseline BP of <120, 120–139, 140–159, and 160 mm Hg or greater

**1° outcome:** Total stroke (fatal or nonfatal)

**Key findings:**
- Smaller BP differences between active vs. placebo groups (p<0.0001) and corresponding lesser risk reductions (p trend=0.05) with lower baseline BPs

**Summary:**
- These analyses provide no evidence of a J-curve relationship between BP level and stroke risk among pts with cerebrovascular disease. However, ischemic stroke, TIA, and hemorrhagic pts were all enrolled and within 5 y of the index event suggesting that these pts were generally neurologically stable and not acknowledging the
between achieved follow-up BP levels and recurrent stroke risk.

**Study type:** Post-hoc analysis of PROGRESS trial.

**Size:** 6,105 pts

Follow-up SBP level was strong and continuous with no evidence of a J-curve in the range of achieved follow-up SBP from 112–168 mm Hg (p trend <0.0001). RR of study treatment on the discontinuation of randomized treatment increased progressively across the subgroups with lower baseline SBP levels at entry (p trend=0.04), but there was no corresponding difference in effects of randomized treatment on the risks of death or hospital admission (both p trend >0.2) or hypotension, renal dysfunction, electrolyte disturbance, hip fracture, or depression between pts with different levels of baseline BP at baseline (all p trend >0.1).

- Minor side-effects were progressively more common at lower BP levels (p homogeneity=0.04).

**Key findings:**
- First analysis showed that the effectiveness of antihypertensive treatment for 2º stroke prevention diminished as baseline BP declined (relative RRs were 39%, 31%, 14%, and 0%, respectively, in the groups defined previously). This trend of decreasing effect was despite successful reduction of mean SBP in each active-treatment group compared with placebo (11.1, 9.2, 7.6, and 7.4 mm Hg reductions, respectively, in the groups defined previously).
- Also of note, 40% of pts with a baseline BP<140 mm Hg were taking antihypertensive therapy at baseline.

**Summary:** Pts ≥75 y with a recent lacunar stroke who achieved a lower SBP target (<130 mm Hg) were significantly more likely to report unsteadiness on standing than their younger counterparts. Lower SBP was not related to a decrease in recurrent stroke risk in elderly pts with lacunar stroke but there was a potential protective advantage from vascular death.
### Ovbiagele B, et al., 2011 (220)

**Aim:** To assess the association of maintaining low-normal vs. high-normal SBP levels with risk of recurrent stroke.

**Study type:** Post hoc analysis of a multicenter trial involving 20,330 pts (age ≥50 y) with recent noncardioembolic ischemic stroke followed up for 2.5 y

**Study Size:** 20,330 pts

**Inclusion criteria:** Pts 55 y or older with an ischemic stroke <90 d before randomization

**Categories:** Based on mean SBP level was very low-normal (<120 mm Hg), low-normal (120≤130 mm Hg), high-normal (130≤140 mm Hg), high (140≤150 mm Hg), and very high (>150 mm Hg).

- **1° outcome:** First recurrence of stroke of any type
- **2° outcome:** Composite of stroke, MI, or death from vascular causes

**Key findings:** Recurrence stroke rates were 8.0% (95% CI: 6.8%–9.2%) for the very low-normal SBP level group, 7.2% (95% CI: 6.4%–8.0%) for the low-normal SBP group, 6.8% (95% CI: 6.1%–7.4%) for the high-normal SBP group, and 14.1% (95% CI: 13.0%–15.2%) for the very high SBP group. Compared with pts in the high-normal SBP group, the risk of 1° outcome was higher for pts in the very low-normal SBP group AHR: 1.29 (95% CI: 1.07–1.56), in the high group AHR: 1.39 (95% CI: 1.08–1.79; p=0.01).

**Relevant 2° endpoint:** Compared with pts in the high-normal SBP group, the risk of 2° outcome was higher for pts in the very low-normal SBP group AHR: 1.31 (95% CI: 1.13–1.52), in the low-normal SBP group AHR: 1.16 (95% CI: 1.03–1.31), in the high SBP group AHR: 1.24 (95% CI: 1.11–1.39), and in the very high SBP group AHR: 1.94 (95% CI: 1.74–2.16).

**Summary:** Among pts with recent noncardioembolic ischemic stroke, SBP levels during follow-up in the very low-normal (<120 mm Hg), high (140–≤150 mm Hg), or very high (≥150 mm Hg) range were associated with increased risk of recurrent stroke.

### Ovbiagele B, et al., 2013 (221)

**Aim:** To assess association of maintaining low-normal vs. high-normal SBP levels with risk of recurrent stroke.

**Study type:** Post hoc analysis of a multicenter trial involving 3,680 pts with recent noncardioembolic ischemic stroke followed up for 2 y

**Study Size:** 3,680 pts

**Inclusion criteria:** Pts with an ischemic stroke <120 d before randomization

**Categories:** Based on mean in-trial SBP value was low-normal (<120 mm Hg), high-normal (120 to <140 mm Hg), or high (>140 mm Hg).

- **1° outcome:** First recurrence of stroke of any type
- **2° outcome:** Stroke, MI, or death from vascular causes

**Key findings:** Rate of recurrent stroke was 9.1% in the low-normal group, 6.7% in the high-normal group, and 10% in the high group. Difference in recurrent stroke rate between low-normal and high-normal groups was more prominent within the first 6 mo (low-normal, 4.5%; high-normal, 2.5%; high, 3.4%) vs. after 6 mo (low-normal, 4.6%; high-normal, 4.2%; high, 6.6%). Over study period, compared with the high-normal group, risk of the 1° outcome trended higher in the low-normal group AHR: 1.47 (95% CI: 0.94–2.29; p=0.09) and was higher in the high group AHR: 1.39 (95% CI: 1.08–1.79; p=0.01).

**Summary:** Results support a possible pattern of increased risk of recurrent stroke in pts with low-normal SBP levels, especially within the first 6 mo after first stroke. However, this study likely was not sufficiently powered to detect more than a strong statistical trend underlying this relationship.

<td>Stratification by quartiles of SBP</td>
<td></td>
<td>Composite of all-cause death or nonfatal vascular event (stroke or AMI); and all-cause death alone.</td>
<td>In 5-y survivors of stroke, compared to a SBP of 131–141 mm Hg, SBP of 120 mm Hg or less was associated with a 61% greater risk of stroke, acute MI and death (HR: 1.61; 95% CI: 1.08–2.41; p=0.019). Compared to the reference category of SBP 131–141 mm Hg, there were no differences in outcome in the pts with SBP 121–130 mm Hg (p=0.491) or 142–210 mm Hg (p=0.313). Findings were not modified after adjusting for antihypertensive drug prescriptions.</td>
<td>There appears to be a greater risk of poor outcome in long-term survivors of stroke with low SBP. This is further evidence that low SBP may result in poor prognosis.</td>
<td></td>

| HOPE Östergren J, et al., 2004 (226) 14683738 | **Aim**: To assess the impact of ramipril compared to placebo on the prevention of major CV events in PAD pts in the HOPE study.  
**Study type**: Multicenter, double-blind RCT  
**Size**: 9,541 randomized in HOPE (1,725 randomized who had baseline PAD, defined by ABI with pulse detection by either Doppler or palpation)  
**Inclusion criteria**:  
- ≥55 y  
- Existing CVD (CAD, stroke, PAD) or DM with an additional CVD risk factor (smoking, HTN, hypercholesterolemia, low HDL, microalbuminuria)  
**Exclusion criteria**:  
- Received ACEI or vitamin E or had uncontrolled HTN  
- HF or LV dysfunction  
*All eligible pts had 7- to 10-d run-in period, received 2.5 mg ramipril daily; those who tolerated were then assigned placebo for 10–14 d and then were randomized to 1 of intervention arms or control | **Intervention**: Ramipril (10 mg/d): 4,645 randomized  
**Intervention**: Placebo: 4,652 randomized | 1° endpoint:  
- Combined CV death, nonfatal MI, nonfatal stroke  
- In pts with history of symptomatic PAD, comparing ramipril to placebo: RR: 0.75; 95% CI: 0.61–0.92  
- In pts with no history of symptomatic PAD, but severe subclinical disease defined as ABI <0.6, comparing ramipril to placebo: RR: 0.77; 95% CI: 0.55–1.09  
- In pts with no history of symptomatic PAD, but moderate subclinical disease defined as ABI 0.6–0.9, comparing ramipril to placebo: RR: 0.72; 95% CI: 0.56–0.92  
1° Safety endpoint: N/A | **Summary**: Ramipril prevented clinical events in pts with clinical evidence of PAD as well as in those without PAD. The relative benefit was similar in pts classified by levels of ABI, even though event rates were higher in pts with subclinical and clinical ABI. | **Relevant 2° endpoint**:  
- Individual components of composite endpoint, all-cause mortality, hospitalizations for HF, DM complications  
- In pts with history of symptomatic PAD, comparing ramipril to placebo: for MI, RR: 0.75 (95% CI: 0.58–0.98); for stroke, RR: 0.72 (95% CI: 0.50–1.05); for CVD mortality, RR: 0.75 (95% CI: 0.56–0.99); for total mortality, RR: 0.85 (95% CI: 0.68–1.07); for DM complications, RR: 0.87 (95% CI: 0.74–1.09); for HF, RR: 0.81 (95% CI: 0.53–1.24)  
- In pts with no history of symptomatic PAD, but severe subclinical disease defined as ABI <0.6, comparing ramipril to placebo: for MI, RR: 0.73 (95% CI: 0.48–1.11); for stroke, RR: 0.99 (95% CI: 0.52–1.89); for CVD mortality, RR: 0.76 (95% CI: 0.46–1.25); for total mortality, RR: 0.81 (95% CI: 0.55–1.19); for DM, RR: 0.83 (95% CI: 0.50–1.39); for HF, RR: 0.66 (95% CI: 0.34–1.28)  
- In pts with no history of symptomatic PAD, but moderate subclinical disease defined as ABI 0.6–0.9, comparing ramipril to placebo: for MI, RR: 0.73 (95% CI: 0.48–1.11); for stroke, RR: 0.99 (95% CI: 0.52–1.89); for CVD mortality, RR: 0.76 (95% CI: 0.46–1.25); for total mortality, RR: 0.81 (95% CI: 0.55–1.19); for DM, RR: 0.83 (95% CI: 0.50–1.39); for HF, RR: 0.66 (95% CI: 0.34–1.28)  
- In pts with no history of symptomatic PAD, but moderate subclinical disease defined as ABI 0.6–0.9, comparing ramipril to placebo: for MI, RR: 0.73 (95% CI: 0.48–1.11); for stroke, RR: 0.99 (95% CI: 0.52–1.89); for CVD mortality, RR: 0.76 (95% CI: 0.46–1.25); for total mortality, RR: 0.81 (95% CI: 0.55–1.19); for DM, RR: 0.83 (95% CI: 0.50–1.39); for HF, RR: 0.66 (95% CI: 0.34–1.28) |

### 2017 Hypertension Guideline Data Supplements

| Size: 98 pts | Inclusion criteria:  
addition risk factor: DM, hyperlipoproteinemia, total or subtotal vascular occlusion of dilated segmented, eccentric stenosis, residual stenosis of at least 30%, or stenosis localized in the distal superficial femoral artery  
Exclusion criteria:  
- History of pelvic stenosis  
- Previous adjuvant therapy with calcium antagonists or beta-adrenergic blocking agents  
- Age >75 y  
- Prior revascularization of same area  
- 1st, 2nd, or 3rd AV block, sinoatrial block, diseases of supporting or connective tissues, moderate arterial HTN with SBP >170 mm Hg and DBP >95 mm Hg  
- Pts requiring stent for large anatomic segments or elastic stenosis  
placebo was 69.6 (SD: 12.2), p<0.01  
1° Safety endpoint: N/A  
Summary: In pts with PAD at increased risk for restenosis, the administration of high dose verapamil prevented recurrent stenosis for 6 mo after successful peripheral angioplasty and was well tolerated.  
Relevant 2° endpoint:  
- Change in ABI measured by Doppler  
- In nebulol: initial ABI 0.62 (SD: 0.16), post-treatment ABI 0.68 (SD: 0.20), p-value for change: 0.002  
- In metoprolol: initial ABI 0.63 (SD: 0.17), post-treatment ABI 0.67 (SD: 0.19)  
- Change in absolute claudication distance were 32.7 m in nebulol (p-value 0.03) vs. 39.7 m in metoprolol (p-value 0.01), but no difference between 2 groups (p-value 0.54)  
- Changes in SBP were -5.2 mm Hg in nebulol (p=0.001) and -3.9 mm Hg in metoprolol (p=0.01), no difference between groups  

| NORMA Espinola-Klein C, et al., 2011 (229)  
21646599 | Aim: Evaluate the effects of treatment with the endothelium-dependent vasodilating beta 1-selective blocker nebulol, as compared with the nonvasodilating beta 1-selective blocker metoprolol, on clinical parameters of PAD and endothelial function, and to compare the  
Inclusion criteria:  
- Stable intermittent claudication for ≥6 mo and an ABI of <0.9  
- Stage 1 arterial HTN (SBP: 140–159 mm Hg, DBP: 90–99 mm Hg untreated, or treated stage 1 arterial HTN)  
- SBP at time of enrollment 100–160 mm Hg  
Intervention arms:  
- Nebivolol (5 mg/d): 65 randomized  
- Metoprolol (95 mg/d): 63 randomized  
1° endpoint:  
- Change in ABI measured by Doppler  
- In nebulol: initial ABI 0.62 (SD: 0.16), post-treatment ABI 0.68 (SD: 0.20), p-value for change: 0.002  
- In metoprolol: initial ABI 0.63 (SD: 0.17), post-treatment ABI 0.67 (SD: 0.19)  
Relevant 2° endpoint:  
- Change in absolute claudication distance were 32.7 m in nebulol (p-value 0.03) vs. 39.7 m in metoprolol (p-value 0.01), but no difference between 2 groups (p-value 0.54)  
- Changes in SBP were -5.2 mm Hg in nebulol (p=0.001) and -3.9 mm Hg in metoprolol (p=0.01), no difference between groups  

© 2017 American College of Cardiology Foundation and American Heart Association, Inc.
### Study type: Double-blinded RCT (48 wk)

**Size:** 128

**Exclusion criteria:**
- DBP at time of enrollment <100 mm Hg
- Critical limb ischemia with rest pain, leg ulcer, gangrene, severe angina pectoris that limits exercise capacity, severe HF that limits exercise capacity, hyperthyroidism, poorly controlled DM (HbA1c >10%)
- Contraindications for BBs
- Acute MI within 6 mo before screening
- Previous treatment with nebivolol or carvedilol

### INVEST

**Aim:** To examine the effect of average treated BP on adverse outcomes in PAD pts with CAD and to compare 2 antihypertensive medications

**Study type:** Post hoc analysis of international

**Inclusion criteria:**
- ≥50 y
- HTN, clinically stable CAD
- Pt reported PAD

**Exclusion criteria:**
- Contraindications to the treatment groups

**Interventions:**
- Calcium antagonist-based strategy: verapamil with or without trandolapril
- BB-based strategy: atenolol with or without hydrochlorothiazide

**1° endpoint:**
- Composite outcome: all-cause death, nonfatal MI, nonfatal stroke
- No statistically significant difference in composite 1° outcome OR: 0.90 (95% CI: 0.76, 1.07) comparing calcium antagonist based group to BB based group in fully adjusted model

**Relevant 2° endpoint:** N/A

**Study limitations and adverse events:**
- Absence of placebo group
- 21 total adverse events, 10 in nebivolol, 11 in metoprolol (adverse events: bradycardia, tachycardia, blurred vision, worsening HTN, edema, worsening claudication, blurred vision, erectile dysfunction, edema, vertigo, temporary dysesthesia of the hands, dyspnea, skin irritation, headache, moderate diarrhea)
randomized, blinded-endpoint trial (48 wk)

**Size:** 22,576 in total trial (2,699 with PAD in this analysis)

**<140/90 mm Hg in all participants except for those with renal impairment or DM, BP<130/85 mm Hg**

- Kaplan–Meier curve for 1° outcome shows slightly lower cumulative incidence in calcium antagonist group (log rank p=0.26)

1st safety endpoint: N/A

**Summary:** Among PAD pts, the incidence of the 1° outcome was not significantly different between treatment groups.

- PAD was not uniformly measured or adjudicated (only based on pt report)
- Asymptomatic PAD was not captured

---

**VALUE**

Zanchetti A, et al., 2006 (231) 17053536

**Aim:** To examine the effect of valsartan vs. amlodipine on cardiac morbidity and mortality in hypertensive pts at high CV risk

**Study type:** Prespecified additional analyses of international randomized, double-blind, parallel-group trial

**Size:** 15,245 in total trial (2,114 with PAD)

**Inclusion criteria:**
- ≥50 y
- HTN (untreated: 160–210/<115 mm Hg, treated: <210/<115 mm Hg)
- High risk for cardiac events (male sex, verified DM, current smoking, high cholesterol, LV hypertrophy by ECG, proteinuria on dipstick, serum creatinine 150–265 micromol/L, coronary disease diagnosis, cerebrovascular disease diagnosis, or PAD diagnosis)

**Exclusion criteria:**
- Renal artery stenosis
- Pregnancy
- AMI, coronary angioplasty or CABC in last 3 mo
- Severe hepatic disease
- Severe chronic renal failure

**Interventions:**
- Valsartan: 7,649 total
- Amlodipine: 7,596 total
  *No PAD-specific numbers available*

**1° endpoint:**
- Composite of sudden cardiac death, fatal MI, death during/after percutaneous coronary intervention or CABC, HF requiring hospitalization, nonfatal MI, or emergency procedure to prevent MI
- There was no significant difference in the 1° outcome by treatment group among all pts and by PAD status. Among pts with PAD, the 1° outcome occurred in 13.4% of valsartan vs. 13.6% of amlodipine pts. Among pts without PAD, the corresponding % were 10.1% and 9.9%.

1st safety endpoint: ---

**Summary:** The effects of treatments on occurrence of the 1° outcome did not differ by PAD status.

| Thompson AM, et al., 2011 (113) 21364140 | To evaluate the effect of antihypertensive treatment on 2° prevention of CVD events and all-cause mortality among pts | RCTs of antihypertensive treatment among pts with BP <140/90 mm Hg for the prevention of CVD events. | Any antihypertensive agent compared with placebo or no treatment. | Compared with controls, pts receiving antihypertensive medications had a pooled RR of 0.77 (95% CI: 0.61, 0.77) for stroke: 0.80 (95% CI: 0.69, 0.96) | PAD not specifically collected at baseline, thus cannot detect actual incidence (however, randomization presumably resulted in equal number of baseline PAD cases in each group) |
|           | Study limitations and adverse events: | PAD not specifically collected at baseline, thus cannot detect actual incidence (however, randomization presumably resulted in equal number of baseline PAD cases in each group) | |

© 2017 American College of Cardiology Foundation and American Heart Association, Inc. 173
without clinically defined HTN.

**Study type:** Meta-analysis including 25 RCTs

**Size:** 64,162 pts without HTN.

**Exclusion criteria:** CVD events were not reported by HTN status that included participants with and without HTN; study population did not include persons with BP in the normal or prehypertensive ranges; study population did not include persons with preexisting CVD or CVD equivalents, such as DM; antihypertensive medication was not a part of the intervention; treatment allocation was not random; measure of variance not reported; participants were <18 y; there were differences between intervention and control groups other than antihypertensive treatment. Preexisting CVD included PAD.

- 0.93) for MI: 0.71 (95% CI: 0.65, 0.77) for CHF: 0.85 (95% CI: 0.80, 0.90) for composite CVD events: 0.83 (95% CI: 0.69, 0.99) for CVD mortality and 0.87 (95% CI: 0.80, 0.95) for all-cause mortality from random effect models. Results did not differ according to trial characteristics or subgroups defined by clinical history, although no specific PAD subgroup was defined.

**Summary:** Among pts with clinical history of CVD, including PAD, but without HTN, antihypertensive treatment was associated with reduced risk of stroke, CHF, composite CVD events and all-cause mortality.

<td>● Fixed combination of perindopril and indapamide compared with perindopril and placebo.</td>
<td>1° endpoints: Composite of CV death, nonfatal MI, nonfatal stroke, new or worsening nephropathy, or retinopathy. <strong>Results:</strong> After 4.3 y follow-up, pts assigned to active therapy had a reduction of SBP of 5.6 mm Hg. RR of major macro- or micro-</td>
<td>● Asymptomatic PAD likely missed (definition used in this study based on hospitalization, likely only capturing very severe cases)</td>
</tr>
</tbody>
</table>
| Study | **DM irrespective of initial BP levels or the use of other BP-lowering drugs.**
| Study type: RCT | **Study type**: RCT
| Size: 11,140 pts, 4.3 y follow-up | **Size**: 11,140 pts, 4.3 y follow-up

**Inclusion criteria:**
- revascularization, or amputation for PVD or at least 1 other risk factor (history of microvascular disease, microalbuminuria, proliferative diabetic retinopathy, retinal photocoagulation therapy, macular edema, blindness, cigarette smoking, high cholesterol, low HDL cholesterol, diagnosis of DM at least 10 y before enrollment or ≥65 y at entry
- **Exclusion criteria:**
  - HbA1c target ≤6.5% or indication for insulin.

**Results:**
- vascular events decreased by 9% (HR: 0.91; 95% CI: 0.83, 1.00), p<0.04. Death from CVD decreased by 18%; RR: 0.82 (95% CI: 0.68, 0.98) and death from any cause decreased by 14%; RR: 0.86 (95% CI: 0.75, 0.98). The effects of study treatment did not differ by initial BP or concomitant use of other treatments at baseline. The pts had at least 1 CV risk factor.

**Limitations:**
- This trial had an open label design. The rate of adverse events in the standard therapy group was less than expected. Pts younger than 40 y or older than 79 y were not included.

**Summary:** In pts with DM-2 and high risk for CV events, targeting SBP of <120 as compared with <140 mm Hg did not reduce the rate of composite outcome of fatal and nonfatal major CV events and was associated with greater risk for adverse events.

---

| Study | **ACCORD**
| Cushman WC, et al., 2010 (234) | **Aim:** To assess whether therapy targeting normal SBP (<120 mm Hg) reduces major CV events in DM-2 at high risk for CV events.
| Study type: RCT | **Study type**: RCT
| Size: 4,733 pts, 4.7 y follow-up | **Size**: 4,733 pts, 4.7 y follow-up

**Inclusion criteria:**
- DM-2 with HgbA1c ≥7.5%; ≥40 y with CVD or ≥55 y with anatomical evidence of atherosclerosis, albuminuria, LVH, or ≥2 additional risk factors for CVD.

**Exclusion criteria:**
- BMI ≥45, serum creatinine >1.5, and other serious illness.

**1° outcomes:**
- Nonfatal MI, nonfatal stroke, or CV death.

**Results:**
- Mean SBP in the intensive therapy group was 119.3 mm Hg and in the standard therapy group was 133.5 mm Hg. The annual 1° outcome 1.87% in the intensive therapy group and 2.09% in the standard therapy group HR: 0.88; 95% CI: 0.073–1.06; p=0.20. The annual rates of death from any cause were 1.28% and 1.19% in the 2 groups, respectively (HR: 0.59; 95% CI: 0.39–0.89; p=0.01). Serious adverse events attributed to antihypertensive treatment occurred in 3.3% of the intensive therapy group and 1.3% of the standard therapy group (p<0.001).

**Limitations:**
- This trial had an open label design. The rate of adverse events in the standard therapy group was less than expected. Pts younger than 40 y or older than 79 y were not included.

**Summary:** In pts with DM-2 and high risk for CV events, targeting SBP of <120 as compared with <140 mm Hg did not reduce the rate of composite outcome of fatal and nonfatal major CV events and was associated with greater risk for adverse events.
| Margolis KL et al., 2014 (235) 24595629 | **Aim:** To compare effects of combinations of standard and intensive treatment of glycemia and BP in the ACCORD trial.  
**Study type:** RCT  
**Size:** 4,733 pts, 4.7 y follow-up | **Inclusion criteria:** Type 2 DM with HgbA1c ≥7.5%; ≥40 y with CVD or ≥55 y with anatomical evidence of atherosclerosis, albuminuria, LVH, or at least 2 additional risk factors for CVD.  
**Exclusion criteria:** BMI >45, serum creatinine >1.5, and other serious illness. | **Pts were randomly assigned to intensive therapy SBP<120 mm Hg or standard therapy SBP<140 mm Hg.**  
**1° outcomes:** Nonfatal MI, nonfatal stroke, or CV death.  
**Results:** In the BP trial, risk of the 1° outcome was lower in the groups intensively treated for glycemia HR: 0.67 (95% CI: 0.50, 0.91), BP HR: 0.74 (95% CI: 0.55, 1.00), or both HR: 0.71 (95% CI: 0.52, 0.96) compared with combined standard BP and glycemia treatment. For 2° outcomes, MI was significantly reduced by intensive glycemia treatment and stroke by intensive BP treatment; most other HRs were neutral or favored intensive treatment groups.  
**Limitations:** 2° analysis; results analyzed across individual cells of a factorial design with shorter follow-up than originally intended reducing power to detect meaningful differences and interactions; results may not apply to younger, healthier diabetics.  
**Conclusions:** Either intensive BP or glycemia control reduced major CVD compared with combined standard treatment, but the combination was no better than the individual intensive interventions. |
| Soliman EZ et al., 2015 (236) 26459421 | **Aim:** To compare effects of combinations of standard and intensive control of BP on the risk of LVH in the ACCORD trial.  
**Study type:** RCT  
**Size:** 4,331 pts, 4.7 y follow-up | **Inclusion criteria:** DM-2 with HgbA1c ≥7.5%; ≥40 y with CVD or ≥55 y with anatomical evidence of atherosclerosis, albuminuria, LVH, or at least 2 additional risk factors for CVD.  
**Exclusion criteria:** BMI >45, serum creatinine >1.5, and other serious illness. | **Pts were randomly assigned to intensive therapy SBP<120 mm Hg or standard therapy SBP<140 mm Hg.**  
**1° outcomes:** Nonfatal MI, nonfatal stroke, or CV death.  
**Results:** The outcome measures were electrocardiographic LVH defined by Cornell voltage (binary variable) and mean Cornell index (continuous variable). The baseline prevalence of LVH (5.3% vs. 5.4%; p=0.91) and the mean Cornell index (1,456 vs. 1,470 µV; p=0.45) were similar in the intensive (n=2,154) and standard (n=2,177) BP-lowering arms, respectively. However, after median follow-up of 4.4 y, intensive, compared with standard, BP lowering was associated with a 39% lower risk of LVH (OR: 0.61; 95% CI: 0.43–0.88; p=0.008) and a significantly lower adjusted mean Cornell index (1,352 vs. 1,447 µV; p<0.001). The lower risk of LVH associated with intensive BP lowering during follow-up was because of more regression of baseline LVH and lower rate of developing new LVH, compared with standard BP lowering. No interactions by age, sex, or race were observed.  
**Limitations:** 2° analysis; open-label design; LVH defined by EKG and not by echo or cardiac MRI; results may not apply to younger, healthier diabetics.  
**Conclusions:** Targeting a SBP of <120 mm Hg when compared with <140 mm Hg in pts with HTN and DM produces a greater reduction in LVH. |
**Aim:** To assess the efficacy and safety of intensive BP lowering strategies.

**Study type:** Systematic review and meta-analysis

**Size:** 19 trials with 44,989 pts; 3.8 y of follow-up.

**Inclusion criteria:**
- RCTs with different BP targets or different BP changes between more vs. less intense therapy with at least 6 mo follow-up.

**Exclusion criteria:**
- Trials that did not assess a different target or relevant outcome.

- 5 RCTs (6,960 pts) enrolled only pts with DM and 6 trials (2,809 pts) specifically recruited pts with CKD.

**1° outcomes:**
- Major CV events, defined as MI, stroke, HF or CV death, separately and combined; nonvascular and all-cause mortality; ESKD; and adverse events; new onset microalbuminuria/macroalbuminuria or change from micro- to macroalbuminuria and retinopathy in pts with DM.

**Results:**
- Pts in the more intensive BP-lowering treatment group had mean BP 133/76 mm Hg compared with 140/81 mm Hg in the less intensive group. Intensive BP-lowering treatment achieved RR reductions for major CV events: 14% (95% CI: 4–22), MI: 13% (95% CI: 0–24), stroke: 22% (95% CI: 10–32), albuminuria: 10% (95% CI: 3–16), and retinopathy progression: 19% (95% CI: 0–34). However, more intensive treatment had no clear effects on HF: RR: 15% (95% CI: -11–34), CV death: 9% (-11–26), total mortality: 9% (95% CI: -3–19), or ESKD: 10% (95% CI: -6–23). The reduction in major CV events was consistent across pt groups, and additional BP lowering had a clear benefit even in pts with SBP <140 mm Hg. The absolute benefits were greatest in trials in which all enrolled pts had vascular disease, renal disease or DM. Serious adverse events associated with BP lowering were only reported by 6 trials and had an event rate of 1%–2% per y in intensive BP lowering group pts, compared with 0.9% in the less intensive treatment group (RR: 1.35; 95% CI: 0.93–1.97). Severe hypotension was more frequent in the more intensive treatment regimen (RR: 2.68; 95% CI: 1.21–5.89; p=0.015), but the absolute excess was small (0.3% vs. 0.1% per pt-y for the duration of follow-up).

**Study limitations:** Only 6,960 pts with DM were included in the total study size of 44,989 pts.

**Conclusions:** The absolute CV benefits were greatest in trials in which all enrolled pts had vascular disease, renal disease or DM. However, only 6,960 of the 44,989 pts had DM and no sub-analysis for DM was provided; however, the outcome benefits were qualitatively most striking for pts with DM, CKD and/or vascular disease.
### ACCOMPLISH
Weber MA, et al., 2010 (237) 20620720

**Aim:** To determine which combination therapy in pts with HTN and DM most effectively decreases CV events.

**Study type:** RCT

**Size:** 2,842 pts with DM from the ACCOMPLISH study of 6,946 pts; 30 mo follow-up

**Inclusion criteria:** HTN and DM with high risk for CV events.

**Exclusion criteria:** BMI >45; serum Cr >1.5; other serious illness

- Pts were randomly assigned to benazepril plus amlodipine or benazepril plus hydrochlorothiazide. BPs were 145/79 at baseline.

**1° outcomes:** Composite of death from CV causes, nonfatal MI, nonfatal stroke, hospitalization for angina, resuscitation after sudden cardiac arrest, and coronary revascularization.

**Results:** The mean achieved BP was 131.5/72.6 and 132.7/73.7 in the B + A and B + H groups, respectively, during the 30 mo of follow-up. There were 8.8% and 11% 1° events, respectively (HR: 0.79; 95% CI: 0.684–0.92; p=0.003). In the pts with DM there were clear coronary benefits with B + A, including both acute clinical events (p=0.013 and revascularizations (p=0.024). There were no unexpected adverse events.

**Summary:** In pts with DM and HTN, combining an ACEI with a CCB, compared with hydrochlorothiazide, was superior in reducing CV events.

### ASCOT
Ostergren J, et al., 2008 (238) 18854748

**Aim:** To compare the effects of an amlodipine-based regimen vs. and atenolol-based regimen on CV outcomes in pts with DM

**Study type:** RCT (BP lowering arm of ASCOT)

**Size:** 5,137 pts with DM, minimum 4 y follow-up

**Inclusion criteria:** Pts 40–65 y with HTN (>160/100 mm Hg) or treated HTN and DM plus 2 additional CV risk factors: PAD, previous stroke or TIA, male sex, ≥55 y, microalbuminuria, smoking, total cholesterol to HDL ratio ≥6, or family history of CHD.

- Pts were randomly assigned to an amlodipine-based regimen with addition of perindopril as required or an atenolol-based regimen with addition of a thiazide as required and therapy titrated as required to achieve target BP of 130/80 mm Hg.

**1° outcomes:** Fatal CHD and nonfatal MI.

**Results:** BPs were 136/75 (amlodipine and 137/76 (atenolol) at the end of study. There was a 3/1.9 mm Hg lower BP in pts on amlodipine. The amlodipine-based regimen reduced CV events and procedures compared to the atenolol-based regimen (HR 0.86; 0.76-0.98; p=0.026). Fatal and nonfatal strokes were reduced by 25% (p=0.017), PAD by 48% (p=0.004) and noncoronary vascularization procedures by 57% (p=0.001).

**Summary:** In the large DM subgroup of the BP-lowering arm of ASCOT, the benefits of an amlodipine-based treatment compared with an atenolol-based treatment on the incidence of total CV events and procedures was significant.

### SHEP
Kostis JB, et al., 2005 (239) 15619390

**Aim:** To assess the long-term mortality rate of pts with DM pts in the SHEP trial randomly assigned to stepped care with chlorthalidone or placebo.

**Inclusion criteria:** Isolated systolic HTN (SBP 160–219 mm Hg) with DBP <90 mm Hg.

**Exclusion criteria:** Pts with insulin–dependent DM and those who

- Pts were randomly assigned to chlorthalidone or placebo. If BP remained above goal, atenolol or placebo was added.

**1° outcomes:** CV mortality rate

**Results:** BP was 11.1/3.4 mm Hg lower in the active treatment group at the end of the study. There was a 3/1.9 mm Hg lower BP in pts on amlodipine. The amlodipine-based regimen reduced CV events and procedures compared to the atenolol-based regimen (HR 0.86; 0.76-0.98; p=0.026). Fatal and nonfatal strokes were reduced by 25% (p=0.017), PAD by 48% (p=0.004) and noncoronary vascularization procedures by 57% (p=0.001).

**Summary:** Chlorthalidone-based treatment improved long-term outcomes in pts with DM.

<td>Aim: To determine if “lower” BP targets (any target &lt;130/85 mm Hg) were associated with a clinically important reduction in the risk of death related to DM, complications related to DM, progression of DM retinopathy and deterioration of visual acuity, but the quality of evidence is low.</td>
<td>Inclusion criteria: RCTs in which individuals were randomly assigned to the 1° outcomes: Total mortality, total serious adverse events, MI, stroke, CHF, and ESRD.</td>
<td>Conclusions: Evidence from RCTs does not support BP targets lower than 130/85 mm Hg.</td>
<td></td>
</tr>
<tr>
<td>mm Hg) are associated with reduction in mortality and morbidity compared to &quot;standard&quot; BP targets (&lt;140–160/90–100 mm Hg) in pts with DM.</td>
<td>randomized to a &quot;lower&quot; compared with a &quot;standard&quot; BP target. <strong>Exclusion criteria:</strong> Studies that did not meet the inclusion criteria. Excluded studies were UKPDS 1998, HTN in Diabetes Study IV 1996, SANDS 2008, Lewis 1999 and the Steno-2 study.</td>
<td>intensive or standard BP control group.</td>
<td><strong>Results:</strong> Only 1 trial (ACCORD) compared outcomes associated with 'lower' (&lt;120 mm Hg) or 'standard' (&lt;140 mm Hg) SBP targets in 4734 pts. Despite achieving a significantly lower BP (119.3/64.4 mm Hg vs. 133.5/70.5 mm Hg, p&lt;0.0001), and using more antihypertensive medications, the only significant benefit in the group assigned to 'lower' SBP was a reduction in the incidence of stroke: RR: 0.58; (95% CI: 0.39–0.88; p=0.009), absolute risk reduction 1.1%. The effect of SBP targets on mortality was compatible with both a reduction and increase in risk: RR: 1.05 (95% CI: 0.84, 1.30), low quality evidence. Trying to achieve the 'lower' SBP target was associated with a significant increase in the number of other serious adverse events: RR: 2.58, (95% CI: 1.70–3.91; p&lt;0.00001, absolute risk increase 2.0%. 4 trials (ABCD-H, ABCD-N, ABCD-2V, and a subgroup of HTN Optimal Treatment) specifically compared clinical outcomes associated with 'lower' vs. 'standard' targets for DBP in pts with DM. The total number of pts included in the DBP target analysis was 2580. Pts assigned to 'lower' DBP had a significantly lower achieved BP: 128/76 mm Hg vs. 135/83 mm Hg; p&lt;0.0001. There was a trend towards reduction in total mortality in the group assigned to the 'lower' DBP target: RR: 0.73 (95% CI: 0.53–1.01), mainly due to a trend to lower non-CV mortality. There was no difference in stroke: RR: 0.67, (95% CI: 0.42–1.05), in MI: RR: 0.95 (95% CI: 0.64–1.40) or in CHF: RR: 1.06 (95% CI: 0.58–1.92), low-quality evidence. End-stage renal failure and total serious adverse events were not reported in any of the trials. A sensitivity analysis of trials comparing DBP targets &lt;80 mm Hg (as suggested in clinical guidelines) than standard targets in pts with HTN and DM.</td>
<td></td>
<td></td>

</tbody>
</table>
| Palmer SC, et al., 2015 (245) 26009228 | **Aim:** To investigate the benefits and harms of BP-lowering drugs in adults with DM  
**Study type:** Network meta-analysis of RCTs.  
**Size:** 157 studies in 43,256 pts mostly with DM and CKD.  
**Mean follow-up:** 4.5 y | **Inclusion criteria:** Pts ≥18 y with DM and CKD and were treated in clinical trials that compared any orally administered antihypertensive agent alone or in combination with a 2nd antihypertensive agent or combination, placebo, or control.  
**Exclusion criteria:** Pts who underwent kidney transplantation or dialysis. | N/A | **1st outcomes:** All-cause mortality and ESKD (need for dialysis or transplantation).  
**Results:** No drug regimen was more effective than placebo for reducing all-cause mortality. However, compared with placebo, ESRD was significantly less likely after dual treatment with an ARB and an ACEI: OR: 0.62 (95% CI: 0.43–0.90) and after ARB monotherapy: OR: 0.77 (95% CI: 0.65–0.92). No regimen significantly increased hyperkalemia or acute kidney injury, although combined ACEI and ARB treatment had the lowest rank among all interventions because of borderline increases in estimated risks of these harms; OR: 2.69 (95% CI: 0.98–7.47) for hyperkalemia; OR: 2.69 (95% CI: 0.98–7.38) for acute kidney injury. | **Limitations:** Effects of BP treatment on CV events and related mortality were uncertain. Data for the outcome of ESKD were restricted largely to pts with macroalbuminuria. Acute kidney injury was poorly defined with low quality of evidence.  
**Conclusions:** No BP-lowering strategy prolonged survival in adults with DM and CKD. ACEIs and ARBs, alone or in combination, were the most effective strategies against ESKD. Any benefits of combined ACEI and ARB treatment need to be balanced against potential harms of hyperkalemia and acute kidney injury. |
| Turnbull F, et al., 2005 (246) 15983291 | **Aim:** To determine the benefits associated with different treatment regimens in pts with and without DM and whether there are important differences in the effects of different BP-lowering regimens in these 2 pt groups.  
**Study type:** Meta-analysis of RCTs.  
**Inclusion criteria:** Randomization of pts between a BP-lowering agent and a control (placebo or less intensive BP-lowering regimen) or randomization of pts between regimens based on different classes of BP-lowering drugs.  
**Exclusion criteria:** Studies not meeting the above criteria. | N/A | **1st outcomes:** Nonfatal stroke or death from cerebrovascular disease; nonfatal MI or death from CAD; HF causing death or requiring hospitalization; total CV events; total CV deaths; and total mortality.  
**Results:** Total major CV events were reduced to a comparable extent in individuals with and without DM by regimens based on ACEIs, calcium antagonists, ARBs and diuretics/BBs (p<0.19 for all). There was limited evidence that lower BP goals produced larger reductions in total major CV events in pts with vs. without DM (p<0.03). | **Limitations:** No analysis of renal outcomes, risk of new DM or progression of existing DM; combined comparison of persons taking diuretics and BBs; some studies selected pts on the basis of the presence or absence of DM.  
**Summary:** Effects of BP-lowering agents on major CV events were broadly comparable for pts with and without DM. |

| ALLHAT Whelton PK, et al., 2005 (247) 15983290 | Aim: To determine the optimal first step antihypertensive drug therapy in DM-2 or impaired fasting blood glucose levels and specifically whether treatment with a CCB or ACEI decreases clinical complications compared to treatment with a thiazide type diuretic.  
Study type: RCT  
Size: 31,512 pts stratified into type 2 DM (13,101), IFG (1,399) and normoglycemia (17,012) | Inclusion criteria: Pts ≥55 y with HTN and at least 1 other risk factor for CHD.  
Exclusion criteria: No history of DM or no fasting glucose measurement or nonfasting glucose level ≥110 mg/dL.  
• Pts were randomly assigned to double-blind first-step treatment with chlorthalidone 12.525 mg/d, amlodipine 2.5–10 mg/d or Lisinopril 10–40 mg/d. | 1° outcomes: Fatal CHD and nonfatal MI  
Results: There was no significant difference in RR (RR) for the 1° outcome in DM or NG pts assigned to amlodipine or lisinopril vs. chlorthalidone or in IFG pts assigned to lisinopril vs. chlorthalidone RR: 1.73 (95% CI: 1.10, 2.72). A significantly higher RR was noted for the 1° outcome in IFG pts assigned to amlodipine vs. chlorthalidone. Stroke was more common in NG pts assigned to lisinopril vs. chlorthalidone RR: 1.31 (95% CI: 1.10, 1.57). HF was more common in DM and NG pts assigned to amlodipine RR: 1.39 (95% CI: 1.22, 1.59) and 1.30 (95% CI: 1.12, 1.51), respectively or lisinopril: 1.15 (95% CI: 1.00–1.32) and 1.19 (95% CI: 1.02, 1.39), respectively vs. chlorthalidone. | Limitations: Microalbuminuria was not measured.  
Summary: Our results provide no evidence of superiority for treatment with CCBs or ACEIs compared with a thiazide-type diuretic during first-step antihypertensive therapy in DM, IFG, or NG. |

</table>
### Study type:
Large meta-analysis of 40 high quality RCTs (1/1966–10/2014) judged low risk of bias.

### Size:
100,354 pts with DM; all trials >1,000 pt-y of follow-up BP-lowering drug vs. placebo: 26 RCTs
- More intensive vs. less intensive BP lowering: 7 RCTs
- BP-lowering vs. another drug: 17 RCTs

### Exclusion criteria:
Trials conducted predominantly in pts with type 1 DM were excluded.

### Results:
Baseline BP: A 10-mm Hg SBP reduction was associated with a significantly lower risk of all-cause mortality RR: 0.87 (95% CI: 0.78–0.96), CVD events RR: 0.89 (95% CI: 0.80–0.98), and stroke events RR: 0.73 (95% CI: 0.64–0.83). The associations for HF and renal failure were not significant. For microvascular events, a 10-mm reduction in SBP was associated with a lower risk of retinopathy RR: 0.87 (95% CI: 0.76–0.99) and albuminuria RR: 0.83 (95% CI: 0.79–0.87).

### Stratified by initial SBP:
Trials stratified by SBP >140 to <140 mm Hg showed significant interactions for all-cause mortality RR: 0.73 (95% CI: 0.64–0.84) vs. 1.07 (95% CI: 0.92–1.26), CVD RR: 0.74 (95% CI: 0.65–0.85) vs. RR: 0.96 (95% CI: 0.88–1.05), CHD RR: 0.73 (95% CI: 0.61–0.87) vs. RR: 0.97 (95% CI: 0.86–1.10), HF RR: 0.75 (95% CI: 0.59–0.94) vs. RR: 0.97 (95% CI: 0.79–1.19) and albuminuria RR: 0.71 (95% CI: 0.63–0.79) vs. RR: 0.86 (95% CI: 0.81–0.99).

### Stratified by achieved SBP:
Trials stratified by SBP achieved in the treatment group ≥130 or <130 mm Hg and the associations of a 10-mm Hg SBP reduction compared between the strata showed significant interactions for all-cause mortality RR: 0.75 (95% CI: 0.65–0.86) vs. RR: 1.06 (95% CI: 0.90–1.265), CVD RR: 0.74 (95% CI: 0.64–0.85) vs. RR: 0.96 (95% CI: 0.88–1.05), CHD RR: 0.70 (95% CI: 0.58–0.83) vs. RR: 0.97 (95% CI: 0.85–1.10), HF achieved SBP levels in the 120–130 mm Hg range. The relatively short follow-up of included trials may have prevented associations of BP-lowering treatment with vascular outcomes from being observed, particularly for outcomes such as HF and renal failure, which are often a consequence of MI or albuminuria, respectively.

### Summary:
- This large meta-analysis of 40 RCTs provides evidence that BP lowering is associated with lower risks of outcomes in pts with initial mean SBP ≥140 mm Hg compared with those <140 mm Hg with the exception of stroke, albuminuria and retinopathy. When trials were stratified by achieved SBP treatment was associated with lower risks only in the <130 mm Hg stratum for stroke and albuminuria.
- This meta-analysis shows that although BP lowering was not associated with a lower risk of CVD or CHD events at a baseline SBP <140 mm Hg, it does observe lower risks of stroke, retinopathy and progression of albuminuria.
- This study provides evidence that for individuals at high risk for these outcomes (history of cerebrovascular disease or mild nonproliferative retinopathy), commencement of therapy below an initial SBP of 140 mm Hg and treatment to SBP <130 may be indicated.

</thead>
</table>
| Cheng J, et al., 2014 (252) 24687000 | **Aim**: To separately evaluate the effects of ACEIs and ARBs on all-cause mortality, CV deaths, and major CV events in pts with DM  
**Study type**: Meta-analysis of 35 high quality RCTs (1966–2012)  
**Size**: 56,444 pts with DM; all trials had follow-up of at least 12 mo. | RCTs including post hoc analyses and subgroups for DM with median follow-up of at least 12 mo. Comparisons with placebo, no treatment or other antihypertensive drugs, including ACEIs and ARBs.  
**Exclusion criteria**: Cross-over trials | • ACEIs significantly reduced the risk of all-cause mortality by 13% (RR: 0.87; 95% CI: 0.78–0.98), CV deaths by 17% (RR: 0.83; 95% CI: 0.70–0.99), and major CV events by 14% (RR: 0.86; 95% CI: 0.77–0.95).  
Including MI by 21% (RR: 0.79; 95% CI: 0.65–0.95) and HF by 19% (RR: 0.81; 95% CI: 0.71–0.93).  
Treatment with ARBs did not significantly affect all-cause mortality (RR: 0.94 [95% CI: 0.82–1.08]), CV death rate (RR: 1.21 [95% CI: 0.81–1.80]) and major CV events (RR: 0.94; 95% CI: 0.85–1.01) with the exception of HF (RR: 0.70; 95% CI: 0.59–0.82). | **Summary**:  
• RCTs comparing ACEs vs. active drugs/placebo/no treatment: 26 RCTs (12 active drugs, 11 placebo)  
• RCTs comparing ARBs vs. active drugs/placebo/no treatment: 13 RCTs (3 active drugs, 10 placebo)  
• This meta-analysis provides evidence that ACEIs reduce all-cause mortality, CV mortality, and major CV events in pts with DM, whereas ARBs had no benefits on these outcomes. |
| Arguedas JA, et al., 2013 (244) 24170669 | **Aim**: To determine if “lower” BP targets (any target <130/85 mm Hg) are associated with reduction in mortality and morbidity compared to “standard” BP targets (<140–160/90–100 mm Hg) in pts with DM.  
**Study type**: Meta-analysis of RCTs. | **Inclusion criteria**: RCTs in which individuals were randomized to a “lower” compared with a “standard” BP target.  
**Exclusion criteria**: Studies that did not meet the inclusion criteria. Excluded studies were UKPDS 1998, HTN in Diabetes Study IV. | **1^ outcomes**: Total mortality, total serious adverse events, MI, stroke, CHF, and ESRD.  
**Results**: Only 1 trial (ACCORD) compared outcomes associated with ‘lower’ (<120 mm Hg) or ‘standard’ (<140 mm Hg) SBP targets in 4734 pts. Despite achieving a significantly lower BP (119.3/64.4 mm Hg vs. 133.5/70.5 mm Hg, p<0.0001), and using more antihypertensive medications, the only significant benefit in the group assigned to ‘lower’ SBP was a reduction in the incidence | **Conclusions**: Evidence from RCTs does not support BP targets lower than standard targets in pts with HTN and DM. |
**Size:** 5 RCTs recruiting a total of 7,314 pts.

**Mean follow-up:** 4.5 y

**Aim:** To assess whether therapy targeting normal SBP (<120 mm Hg) reduces major of stroke: RR: 0.58 (95% CI: 0.39–0.88; p=0.009), absolute risk reduction 1.1%. The effect of SBP targets on mortality was compatible with both a reduction and increase in risk: RR: 1.05 (95% CI: 0.84–1.30), low-quality evidence. Trying to achieve the 'lower' SBP target was associated with a significant increase in the number of other serious adverse events: RR: 2.58 (95% CI: 1.70–3.91; p<0.00001), absolute risk increase 2.0%. 4 trials (ABCD-H, ABCD-N, ABCD-2V, and a subgroup of HOT) specifically compared clinical outcomes associated with 'lower' vs. 'standard' targets for DBP in pts with DM. The total number of pts included in the DBP target analysis was 2580. Pts assigned to 'lower' DBP had a significantly lower achieved BP: 128/76 mm Hg vs. 135/83 mm Hg, p<0.0001. There was a trend towards reduction in total mortality in the group assigned to the 'lower' DBP target: RR: 0.73 (95% CI: 0.53–1.01), mainly due to a trend to lower non-CV mortality. There was no difference in stroke: RR: 0.67 (95% CI: 0.42–1.05), in MI: RR: 0.95 (95% CI: 0.64–1.40) or in CHF: RR: 1.06 (95% CI: 0.58–1.92), low quality evidence. End-stage renal failure and total serious adverse events were not reported in any of the trials. A sensitivity analysis of trials comparing DBP targets <80 mm Hg (as suggested in clinical guidelines) vs. <90 mm Hg showed similar results. There was a high risk of selection bias for every outcome analyzed in favor of the 'lower' target in the trials included for the analysis of DBP targets.

**Inclusion criteria:** Type 2 DM with HgbA1c ≥7.5%; ≥40 y with CVD or ≥55 y with anatomical evidence of Pts were randomly assigned to intensive therapy SBP<120 mm Hg or standard therapy SBP<140 mm Hg.

**Limitations:** This trial had an open label design. The rate of adverse events in the standard therapy group was less than...
CV events in type 2 DM at high risk for CV events.

**Study type:** RCT  
**Size:** 4,733 pts, 4.7 y follow-up

diabetes mellitus, atherosclerosis, albuminuria, LVH, or at least 2 additional risk factors for CVD.

**Exclusion criteria:** BMI ≥45, serum creatinine >1.5, and other serious illness.

**1° outcomes:** Nonfatal MI, nonfatal stroke, or CV death.

**Results:** Mean SBP in the intensive therapy group was 119.3 mm Hg and in the standard therapy group was 133.5 mm Hg. The annual 1° outcome 1.87% in the intensive therapy group and 2.09% in the standard therapy group HR: 0.88 (95% CI: 0.073–1.06; p=0.20). The annual rates of death from any cause were 1.28% and 1.19% in the 2 groups, respectively (HR: 0.59; 95% CI: 0.39–0.89; p=0.01). Serious adverse events attributed to antihypertensive treatment occurred in 3.3% of the intensive therapy group and 1.3% of the standard therapy group (p<0.001).

**Summary:** In pts with type 2 DM and high risk for CV events, targeting SBP of <120 as compared with <140 mm Hg did not reduce the rate of composite outcome of fatal and nonfatal major CV events and was associated with greater risk for adverse events.

Hartley L, et al., 2014 (253) 25436436

**Aim:** To determine the effectiveness of transcendental meditation for the 1° prevention of CVD  
**Study type:** Literature review of RCTs  
**Size:** 4 trials with a total of 430 pts

**Inclusion criteria:** ≥3 mo duration, healthy adults or adults at high risk of CVD, comparison of no or minimal intervention.  
**Exclusion criteria:** Multi-factorial interviews

**1° outcomes:** Clinical CVD events and major CVD risk factors

**Results:** No conclusions of the effectiveness of transcendental meditation for the 1° prevention of CVD

**Limitations:** Limited evidence

**Summary:** No conclusions as to the effectiveness of transcendental meditation for the 1° prevention of CVD. There was considerable heterogeneity between trials and the included studies were small, short-term, and at overall serious risk of bias.

**Summary:** N/A

Lv, et al., 2013 (127) 23798459

**Aim:** To assess the renal and CV effects of intensive BP lowering in people with CKD  
**Study type:** Systematic review  
**Size:** 9,287 pts with CKD and 1,264 kidney failure events

**Inclusion criteria:**  
- Randomized trials of pts with CKD assigned to different target BP that reported kidney failure and CV events.  
- 11 trials on 9,287 pts with CKD and 1,264 kidney failure events (doubling of serum creatinine, 50% decline in GFR or ESKD)  
- Included AASK, REIN-2,

**Results:** Compared with standard regimens, more intensive BP lowering reduced risk of composite endpoint HR: 0.82 (95% CI: 0.68–0.98) and ESKD HR: 0.79 (95% CI: 0.67–0.93). Effect was modified by proteinuria (p=0.006) and markers of trial quality. Intensive BP lowering reduced the risk of kidney failure HR: 0.73 (95% CI: 0.62–0.86) but not in pts without proteinuria at baseline HR: 1.12 (95% CI: 0.67–1.87). No clear effect on CV events or death.

**Limitations:** All trials used open label, in 2 pts were blinded, substantial variability in design quality. There was substantial variability in BP targets by MAP, SBP and DBP or only DBP. Most trials did not include pts with diabetic kidney disease

**Summary:**  
- Renal outcomes: 7 trials (N=5308) recorded a total of 1,264 kidney failure events. A -7.7 mm Hg difference in SBP and a -4.9 mm Hg
MDRD, Wuhl (children), Toto, Schrier plus 5 trials with CKD subgroups, also included the late nonrandomized follow-up studies for AASK and MDRD

- BP targets varied substantially between trials. 2 trials targeted mean BP <92 mm Hg for the intensive treatment arm, and 107 mm Hg in the standard treatment arm. 1 trial aimed for BP <130/80 mm Hg vs. a DBP of 90 mm Hg, 1 study targeted <120/80 mm Hg vs. 135–140/85–90 mm Hg, and 4 studies had DBP <75–80 mm Hg vs. from 80–90 mm Hg. A trial involving pediatric pts targeted a 24-h mean BP <the 50th percentile, compared with the 50th to 95th percentiles in the control group. 2 trials had more liberal targets for intensive treatment (<140–150 mm Hg SBP, 85 mm Hg DBP)

- difference in DBP seen between treatment arms. Overall, a more intensive regimen reduced risk of composite kidney failure events by 17% (HR: 0.82; 95% CI: 0.68, 0.98), reduced the risk of ESKD alone by 18% (pooled HR for composite outcomes: 0.79; 95% CI: 0.67, 0.93).
- Intensive BP lowering had no effect on kidney failure in pts who did not have proteinuria (3 trials involving 1,218 pts (HR: 1.12; 95% CI: 0.67–1.87), but it did reduce the risk of progressive kidney failure by 27% (5 trials involving 1,703 pts (HR: 0.73; 95% CI: 0.62–0.86) in pts who did have proteinuria at baseline.
- CV outcomes: major CV events reported in 5 trials (472 CV events in 5,308 pts with CKD). Intensive BP lowering did not reduce risk of CV events in pts with CKD, but the CIs remained wide (RR: 1.09 (95% CI: 0.83, 1.42). 6 trials reported stroke outcomes (197 events in 5,411 pts), 5 trials reported MI (138 events in 4,317 pts), and 5 trials reported HF (118 events in 5,308 pts). They saw no clear effect of intensive treatment on any of these vascular outcomes.
- Death: 10 trials involving 6,788 pts reported 846 deaths. There was no clear effect of intensive BP lowering on risk of all-cause death (RR: 0.94 (95% CI: 0.84, 1.05) or CV death (RR: 1.20 (95% CI: 0.82, 1.75).

| Healey et al., 2005 (257) 15936615  | **Aim**: Systematic review of all RCT evaluating the benefit of trials of ACEI and ARBs in prevention of AF | **Study type**: Meta-analysis | **Intervention**: n=27,089 RAAS blockade  
**Comparators**: n=29,220 placebo or active control antihypertensive | **Inclusion criteria**: Studies of RAAS blockade in CHF, MI, electrical cardioversion, and HTN with incidence of AF noted during follow-up  
**Exclusion criteria**: Studies without the measurement of AF or use of RAAS blockade. | **1° endpoint**: AF occurrence or reoccurrence | • ACEIs and ARBs reduced RR of AF by 28% (p=0.0002), greatest in pts with HF [RR reduction: 44%; p=0.007]. No significant reduction in AF in pts with HTN [RR reduction: 12%; p=0.4], but 1 trial found a significant 29% reduction in pts with LVH. Following cardioversion there was a large effect (48% RR reduction; 95% CI: 21%–65%). | • ACEIs and ARBs appear to be effective in prevention of AF probably limited to pts with systolic LV dysfunction or HTN LVH |
| Jibrini et al., 2008 (255) 18223352 | **Aim**: To assess the effectiveness of ACEIs and ARBs in the prevention of AF, and to identify those clinical entities in which RAAS inhibition would most likely benefit the pts. | **Study type**: Meta-analysis | **Intervention**: n=26,973 RAAS blockade  
**Comparators**: n=29,016 placebo, amlodipine, BB or thiazide diuretic | **Inclusion criteria**: Studies of RAAS blockade in CHF, MI, electrical cardioversion, and HTN with incidence of AF noted during follow-up  
**Exclusion criteria**: Studies without the measurement of AF or use of RAAS blockade. | **1° endpoint**: AF occurrence or reoccurrence. | • Treatment with RAAS blockers reduced RR of AF in pts with HTN by 23% (p<0.001), by 11% in pts after MI (p<0.05), by 51% after electrical cardioversion (p<0.001), by 32% in pts with HF (p<0.001) and by 19% overall (p<0.001). | N/A |
### Zhao et al., 2015 (256)

| **Intervention:** | RAAS blockade, n=20,491 |
| **Comparator:** | BB/calcium antagonist, n=22,401 |
| **Inclusion criteria:** | RCTs on the effects of ACEI/ARBs on essential hypertensive pts. |
| **Exclusion criteria:** | Non-RCTs, subjects who were not treated with ACEI or ARB, and trials not mentioning of AF prevention. |
| **1° endpoint:** | AF occurrence or reoccurrence. |

- ACEI/ARBs reduced the incidence of AF recurrence compared to calcium antagonists (RR: 0.48; 95% CI: 0.40–0.58; p<0.00001) or b-blockers (RR: 0.39; 95% CI: 0.20–0.74; p=0.005). ACEI/ARBs may reduce the incidence of AF recurrence and CHF, with fewer serious adverse effects, but did not prevent new onset of AF.

### Hansson et al., 1999 (258)

| **Intervention:** | Captopril, n=5,592 |
| **Comparator:** | 5,493 pts were allocated to diuretics or BBs |
| **Inclusion criteria:** | Pts aged 25–66 y with a measured DBP of ≥100 mm Hg on 2 occasions were included. |
| **Exclusion criteria:** | 2º HTN, serum creatinine concentration of more than 150 micromol/L, and disorders that required treatment with BB. |
| **1° endpoint:** | Fatal and nonfatal MI and stroke, and other CV deaths. |
| **2° endpoint:** | New or deteriorated IHD and CHF, AF, DM, TIA s, and death from all causes. |

- Captopril and conventional treatment did not differ in rates of all cardiac events—fatal and nonfatal MI, other CV deaths and sudden deaths, IHD, CHF, or AF (0.94; p=0.30).

### Hansson et al., 1999 (259)

| **Intervention:** | n=2205 pts treated with ACEI |
| **Comparator:** | n=2,213 pts treated with BB or diuretic combination or n=2,196 pts treated with CCB |
| **Inclusion criteria:** | HTN with BP ≥ 180 mm Hg systolic, aged 70–84 y |
| **Exclusion criteria:** | Outside of the age range (n=14) |
| **1° endpoint:** | CV death |
| **2° endpoint:** | CV events, DM and AF |

- Old and new antihypertensive drugs were similar in prevention of CV mortality or major events. Decrease in BP was of major importance for the prevention of CV events. No difference in AF frequency was found (5.3% with ACEI, 4.1% with CCB and 5.2% with older drugs).
### Wachtell et al., 2005 (260)

**Study type:** RCT  
**Size:** 6,614

**Aim:** LIFE trial aimed to determine whether angiotensin II receptor blockade is better than beta-blockade in preventing new-onset AF.

**Intervention:**  
- n=4,298 treated with losartan  
- Comparator: n=4,182 treated with atenolol

**Inclusion criteria:**  
- Hypertensive pts with LVH by echo

**Exclusion criteria:**  
- Prior AF history in 342 pts

**1° endpoint:** new onset of AF  
- • New-onset AF occurred in 150 pts randomized to losartan vs. 221 to atenolol (6.8 vs.10.1 per 1,000 person-y; RR: 0.67; 95% CI: 0.55–0.83; p<0.001) despite similar BP reduction. Pts receiving losartan tended to stay in sinus rhythm longer (p=0.057) than those receiving atenolol.

**2° endpoint:** None

### Haywood et al., 2009 (261)

**Study type:** RCT  
**Size:** 9,193

**Aim:** To investigate incidence of development of AF/AFL in pts enrolled in this comparative trial of antihypertensives (ALLHAT).

**Intervention:**  
- n=42,418 on diuretics  
- Comparator: n=39,056

**Inclusion criteria:**  
- Essential HTN with BP >140/90 without medications, >180 systolic if on medications

**Exclusion criteria:**  
- Not meeting inclusion criteria

**1° endpoint:** ECG evidence of AF/AFL on follow-up of HTN and dyslipidemia  
- • AF/AFL occurred in 641 pts on follow-up. Incidence did not differ by class of antihypertensive, other than increased frequency in the doxazosin group by 33% vs. chlorthalidone group (p=0.05 after risk adjustment).

**2° endpoint:** None  
- • Doxazosin group was limited by higher cardiac event rates and early termination of this portion of the trial.

### Julius et al., 2004 (Julius, 2004)

**Study type:** RCT  
**Size:** 81,474

**Aim:** The Valsartan Antihypertensive Long-term Use Evaluation (VALUE) trial: does valsartan reduce cardiac morbidity and mortality more than amlopidine for the same degree of BP reduction in in hypertensive pts at high CV risk.

**Intervention:**  
- n=7,649 on valsartan  
- Comparator: n=7,596 on amlopidine

**Inclusion criteria:**  
- Hypertensive pts, ≥50 y with DM, current smoking, high total cholesterol, LVH by ECG, proteinuria on dipstick and CKD (not end-stage)

**Exclusion criteria:**  
- ESRD, renal artery stenosis, pregnancy, AMI, PTCA or CABG within the past 3 mo, clinically

**1° endpoint:** Cardiac mortality, morbidity, HF, stroke, all-cause death, new onset DM  
- • AF occurred in 2.4% with valsartan and 2.0% with amlopidine; p=0.1197.

**Safety endpoint:** Hypertension, syncope

**2° endpoint:** AF

</table>

**Exclusion criteria:** Major ones included DM, history of stroke, ESRD (eGFR <20)

**Adverse events:**
- SAEs: 1.04; p=0.25
- Significant absolute increases seen in intensive group for hypotension (1%), syncope (0.6%), electrolyte abnormality (0.8%), acute kidney injury/acute renal failure (1.6%) over the study period.
- 1.7% fewer pts had orthostatic hypotension in intensive group; p=0.01.

**Limitations:** Few participants were untreated at baseline ~9%, so SPRINT provides little if any insight at present regarding BP-lowering medication initiation for untreated people with SBP 130–139.

| CLUE Peacock WF, et al., 2011 (284) 21707983 | Aim: Compare safety and efficacy of IV nicardipine vs. labetalol in the management of acute HTN.  
Study type: RCT | Inclusion criteria: SBP ≥180 mm Hg on 2 consecutive occasions 10 min apart in the ED.  
  • 110 pts randomized to nicardipine; 116 to labetalol. End-organ damage preceded randomization in 63% with no difference between the groups. The target BP range (TR; at the discretion of the | Results: Within 39 min, nicardipine pts reached TR than labetalol pts (91.7 vs. 82.5%; p=0.039). Of 6 BP measurements taken 5 min apart, nicardipine pts had a higher rate of 5 and 6 SBP measures in the TR than labetalol pts (47.3 vs. 32.8%; | Limitations: Study unblinded; large number of pts without end-organ damage (which usually defines a hypertensive emergency); physicians ordered fewer dose titrations of labetalol than nicardipine; thus, lack of BP decline might have been due to insufficient dosing by physicians hesitant to administer successively increasing doses of labetalol as recommended by the FDA. |
| | | | | | Conclusions: Intensive SBP is safe and effective for lowering CVD events and total mortality in adults ≥75 y |
### Liu-DeRyke X, et al., 2013 (285)  23760911

**Aim:** Compare ability of IV nicardipine and labetalol to lower BP in acute hemorrhagic or ischemic stroke.

**Study type:** RCT (pseudo-randomization)

**Size:** 54 pts

**Inclusion criteria:** Pts with acute hemorrhagic or ischemic stroke who were at or exceeded AHA guidelines BP recommendations.

**Exclusion criteria:** Traumatic brain injury; intracranial neoplasm, received antihypertensive medication within previous 24 h, brain stem herniation, immediate brain death, acute MI, or bradycardia <50 bpm.

- 28 pts randomized to labetalol and 26 to nicardipine. Goal BP defined using the latest consensus recommendations.

**Results:** All pts receiving nicardipine achieved BP goal Compared with 61% in the labetalol group (p<0.001). 89% of the nicardipine group achieved goal within 60 min vs. 25% in the labetalol group (p<0.001). The nicardipine group had better maintenance of BP, greater percent of time spent within goal and less BP variability compared with the labetalol group (p<0.001). Less rescue medication had to be given to the nicardipine than the labetalol group (p<0.001).

**Limitations:** Very small; pseudo-randomization.

**Conclusions:** In acutely hypertensive stroke pts, a superior BP-lowering response was achieved with nicardipine over labetalol. Despite this, there was no significant difference in clinical outcomes.

### CATIS

He J, et al., 2014 (202)  24240777

**Aim:** Evaluate whether immediate BP reduction in pts with acute ischemic stroke would reduce death and major disability in 14 d or hospital discharge.

**Study type:** RCT

**Size:** 4,071 pts

**Inclusion criteria:** Pts had nonthrombolysed ischemic stroke within 48 h of onset and elevated SBP. Baseline SBP was 166.7 mm Hg in the antihypertensive treatment group and 165.6 mm Hg in the control group.

- This was a Chinese multicenter, single-blinded, blinded endpoints RCT conducted in 26 hospitals in China. 2,038 pts were randomized to receive antihypertensive treatment and 2,033 were randomized to the control group. The trial was designed to test a BP

**Results:** In the antihypertensive treatment group, SBP was reduced from 166.7 to 144.7 mm Hg (-12.7%) within 24 h and in the control group from 165.6 to 152.9 mm Hg (-7.2%) (absolute difference -9.1 mm Hg; 95% CI: -10.2– -8.1; p<0.001). Mean SBP was 137.3 mm Hg in the antihypertensive treatment

**Limitations:** Study excluded pts with BP ≥220/120 mm Hg, so the results do not apply to such pts. Pts treated acutely with thrombolytic therapy were excluded. Trial performed exclusively in Chinese pts.

**Conclusions:** Among pts with acute ischemic stroke, BP reduction with antihypertensive medications, compared to absence of antihypertensive medications, did not reduce the likelihood of death and major disability at 14 d or hospital discharge.
reduction strategy rather than the efficacy of specific antihypertensive drugs. Pts in the control group discontinued their home BP medications.

1° outcome: Combination of death and major disability at 14 d or hospital discharge.

group and 146.5 mm Hg in the control group at the 7th d of randomization (absolute difference -9.3 mm Hg; 95% CI: -10.1–-8.4; p<0.001). The 1° outcome did not differ between treatment groups (OR: 1.00; 95% CI: 0.88–1.14) at 14 d or hospital discharge. The 2° outcome of death and major disability at 3 mo post-treatment follow-up did not differ between the groups.

INTERAC-2
Anderson CS, et al., 2013 (191)
Study type: RCT
Size: 2,839 pts

To compare the management strategy of targeting SBP<140 mm Hg within 1 h with the current guideline strategy of targeting SBP to <180 mm Hg with the use of agents of the physicians’ choosing.

This was an international, multicenter, prospective randomized open-treatment, blinded endpoint trial. The pts had onset of spontaneous ICH within 6 h of enrollment.

1° outcome: Death or major disability, defined as a score of 3-6 on the modified Rankin scale, at 90 d.

Results: 719 of 1,382 pts receiving intensive treatment as compared to 785 of 1,412 pts receiving guideline-recommended treatment had a 1° outcome event [OR with intensive treatment: 0.87; 95% CI: 0.75–1.01; p=0.06]. Ordinal analysis showed significantly lower modified Rankin scores with intensive treatment (OR for greater disability: 0.87; 95% CI: 0.77–1.00; p=0.04). Mortality was 11.9% in the group receiving intensive treatment and 12.0% in the group receiving guideline-recommended treatment. Nonfatal serious events were not significantly different between the groups.

Limitations: No major limitations.

Conclusions: In pts with ICH, intensive lowering of BP resulted in a borderline significant reduction in the rate of death or severe disability at 90 d. An ordinal analysis of modified Rankin scores indicated improved functional outcomes with intensive lowering of BP. Intensive BP reduction was shown to be safe and to result in significantly better health-related quality of life.

<td>Exclusion criteria: History and/or signs of major CVDs (e.g., previous MI, coronary artery surgery, major arrhythmias, conduction defect, recent stroke, carotid artery disease, ≥2 TIA and signs or symptoms in a single neurological distribution); other major diseases (e.g., cancer, alcoholic liver disease, established renal dysfunction) with competing risk factors for the 1° endpoint; stroke; presence of medical management problems (e.g., insulin dependent DM, history of dementia, evidence of alcohol abuse); bradycardia; people maintained on BBs, diuretics, other antihypertensive drugs, anticoagulants.</td>
<td>Comparator: Placebo</td>
<td>Cases: Active: 37 Placebo: 44 p=0.84 (0.54,1.31) No cognitive function instrument included in trial</td>
<td>Summary: Nonsignificant 16% lower incidence of incident instrumental activity of daily living disability. However, assignment to the placebo group and the resulting occurrence of CV events independently predicted missed assessments. However, when 20%–30% and 40%–80% of the subjects who missed the assessment were assumed to be cognitively/functionally impaired, assignment to active treatment reduced the risk of these outcomes. Thus, in the SHEP study, the cognitive and functional evaluations were biased toward the null effect by differential dropout. This might have obscured the appraisal of a protective effect of treatment on the cognitive and functional decline of older hypertensive adults.</td>

**COMFORT**
Matsumura K, et al., 2012 (306) 22447014

**Aim:** Evaluate whether a combination pill of antihypertensive drugs improves medication adherence in hypertensive pts vs. use of single agents.

**Study type:** Multicenter, open, RCT at 29 sites in Japan. Adherence assessed by pill count.

**Size:** 207 pts

**Inclusion criteria:**
- ≥20 y agent with HTN
- Could be treated with an ARB and diuretic

**Exclusion criteria:**
- Extremely high BP (≥200 mm Hg SBP or ≥120 mm Hg DBP)
- Serious renal or liver dysfunction
- Taking >4 tablets, excluding study drugs

**Intervention:** Combination tablet of (Losartan 50 mg/HCTZ 12.5 mg; n=103)

**Comparator:** ARB and a thiazide diuretic as separate agents (n=104)

**1° endpoint:** Adherence rates as assessed by pill count 98% in both groups (p=0.89) over entire study period (0–6 mo).

**Safety endpoint:** No differences in serious adverse events (1% vs. 1%; p=0.99) or mild adverse events (6% vs. 10%; p=0.31)

**2° endpoint:** No significant difference in mean SBP and DBP (0.3 and 0.1 mm Hg respectively; p=0.84/0.96).

**Study limitations:**
- Adherence rate very high for both groups and likely does not represent real-world rates.
- Short duration (6 mo) and thus does not provide much information on medication persistence (continuation of drug therapy long-term)
- Possible selection bias with 2 run-in phases
- Different healthcare system (Japan) with medications provided through public medical insurance

---

  - Database search for all RCTs, all languages, in Cochrane Controlled Trials Register, MEDLINE, EMBASE, and CINAHL (all y through 2002)
  - Population of interest were pts with essential HTN in primary care, outpatient, or community setting
  - Interventions aimed to increase adherence to BP-lowering medication
  - Reported outcome was adherence | **1° endpoints:** Adherence as assessed by pill counts, self-report, or electronic monitoring system
  **Results:**
  - 9 studies assessed simplification of dosing regimen, 7 of which compared adherence associated with frequency of administration (twice daily vs. once daily [n=6] or 3 times daily vs. twice daily [n=1]).
  - All studies examining effect of dosing frequency demonstrated improved adherence (range: 8%, 19.6% improvement; p<0.01 for all).
  **2° endpoints:** Adherence to antihypertensive medication was significantly improved with once daily vs. multiple daily dosing regimens. Most studies used an electronic monitoring system. Limitations in the systematic review include heterogeneity in pts, interventions, and outcomes, and the majority of studies were of low quality. In addition, different definitions of adherence in the RCTs make it difficult to examine the precise relationship of adherence to BP control. |

<tbody>
<tr>
<td>Size: 76 studies</td>
<td>Compliance rates assessed using electronic monitoring device</td>
<td></td>
<td>For all studies, mean dose-taking compliance defined as number of appropriate doses taken during each d was 79% for once daily, 69% for twice daily, 65% for 3 times daily and 51% for 4 times daily dosing (p&lt;0.001 for once daily vs. 3 times daily, once daily vs. 4 times daily, and twice daily vs. 4 times daily; no statistically significant between once daily vs. twice daily or twice daily vs. 3 times daily dosing).</td>
</tr>
<tr>
<td>Inclusion criteria:</td>
<td>Data pooled to calculate mean compliance with once daily, twice daily, 3 times daily, and 4 times daily dosing regimens</td>
<td></td>
<td>Medication compliance as measured by electronic monitoring devices were improved with less frequent dosing. Once-daily dosing was associated with the greatest rate of compliance. Limitations of this analysis include heterogeneity of studies and disease states studied.</td>
</tr>
</tbody>
</table>
For 14 studies that assessed ability to take doses within prescribed time frame, once daily regimens were associated with better dose-time compliance (74% ± 31%) compared to twice daily (58% ± 23%) or 3 times daily (46% ± 8%); formal statistical analysis not conducted due to too few studies.

**Sherrill B, et al., 2011 (310)**

**Study type:** Meta-analysis to compare health resource use cost, adherence, and persistence between groups of pts taking antihypertensives as SPCs vs. free-equivalent components.

**Size:** 15 retrospective database studies in HTN

**Inclusion criteria:**
- Database search of PubMed, EMBASE, The Cochrane Library, and EconLit (no limit on publication dates)
- English-language publications
- Clinical trial or observational study (e.g., database or registry) that compared SPC with free-equivalent components
- Data on compliance, adherence, persistence, and/or health care costs and/or resource use (unadjusted cost analyses)

**1° endpoints:** Health care costs, adherence, persistence

**Results:**
- All-cause total costs were estimated to be lower with SPC vs. free-equivalent components free-equivalent components by $2,039 (95% CI: $1030, $3047) in 2009 dollars and HTN/CV-related costs were lower by $709 (95% CI: $117, $1,032), 2009 dollars.
- Adherence as measured by MPR was greater for SPC vs. free-equivalent components (total inverse variance 13.31; 95% CI: 8.26–18.35).
- Persistence to therapy was greater with SPC than free-equivalent components (risk ratio: 2.13; 95% CI: 1.11–4.09)

- Medication adherence and persistence was significantly greater with SPC than free-equivalent components. Costs were also significantly lower with SPC than with free-equivalent components. However, cost data should be interpreted with caution considering unadjusted costs were used in this meta-analysis. In addition, heterogeneity was present in analyses of each outcome. This meta-analysis did not include the observational study by Yang et al. as that study used an adjusted analysis methodology.

**Yang W, et al., 2010 (311)**

**Study type:** Observational analysis using multivariate regression-adjusted analysis to compare compliance/persistence, health care resources, and cost associated with SPC or FC antihypertensives over 6 mo study period both nationally and at the state level.

**Size:** 579,581 pts (382,476 SPC and 197,375 FC) identified in MarketScan Database (2006–2008)

**Inclusion criteria:**
- Pts in MarketScan Database
- Diagnosis of HTN based on ICD-9 codes 401.xx and 405.xx
- Pts initiated on any of the following SPC treatments or the same FC: ARB + CCB, ARB + HCTZ, ACEI + HCTZ
  - For SPC cohort, at least 1 prescription filled in observational window
  - For FC cohort, pts filled individual components separately within 15 d of each other and with 15 d overlap of supply
  - ≥18 y

**Endpoints:**
- 1° outcome: Compliance and persistence with the index therapy (SPC or FC) measured by MPR within 6 mo of index date
- 2° outcomes: Healthcare resource utilization (number of all-cause hospitalizations, number ER visits, number CV hospitalizations, and CV-related ER visits) and health care costs (all cause medical costs, all-prescription drug costs, CV-related medical service costs, and HTN prescription-related drug costs)

**Results:**
- Compliance nationally as assessed by MPR was improved in pts taking SPC vs. FC antihypertensives (difference=11.6%; 95% CI: 11.4%–11.7%).

- This large observational study found that medication compliance/persistence to antihypertensives was improved with SPC compared to FC using an adjusted multivariate regression model. All-cause medical costs were also decreased with the used of SPC antihypertensives, although prescription costs were greater.

| Meta-analysis to assess compliance, adherence, persistence, BP control, and safety with FDC antihypertensives compared to their free components | Database search of PubMed (1966–February 2008), Web of Science (1970 to April 2008), and the Cochrane Controlled Trial (1800–April 2008). Clinical trials or cohort studies included if published in English and compared an FDC of hypertensive agents with free-drug combination of its components. Extractable data reported including compliance (or adherence), persistence, BP-lowering effects, adverse effects. | Compliance (or adherence) and persistence to therapy | Use of FDC therapy was associated with a 21% increase in compliance, both in the cohort studies (n=5) and clinical trials (OR: 1.21; 95% CI: 1.00–1.47) and (OR: 1.21; 95% CI: 1.03–1.43). There was a 50% increase in persistence with therapy, but this was not statistically significant (OR: 1.54; 95% CI: 0.95–2.49). Analysis of all 6 retrospective cohort studies indicated that FDC therapy was associated with a 29% increase in compliance and persistence to therapy (OR: 1.29; 95% CI: 1.11–1.50). No sign of heterogeneity of publication bias. FDC therapy was associated with a nonsignificant reduction in SBP (-4.1 mm Hg; 95% CI: -9.8–1.5 mm Hg; p=0.15) and DBP (-3.1 mm Hg; 95% CI: -7.1–0.9 mm Hg; p=0.13) compared to free-drug combinations. Strong evidence of heterogeneity but no evidence of publication bias. FDC therapy was associated with a 20% nonsignificant decrease in adverse effects (OR:...

Gupta, et al., 2010 (312) 20026768

- Continuous eligibility in database for 6 mo after index date
- Valid 3-digit zip code in database
- Treatment discontinuation rates were lower with SPC vs. FC antihypertensives (40.7% vs. 59.3%; 95% CI: 0.46–0.48).
- There were fewer all-cause hospitalizations and ER visits in SPC vs. FC pts IRR: 0.77 (95% CI: 0.75–0.79) and IRR: 0.87 (95% CI: 0.86, 0.89), respectively.
- All-cause medical costs were reduced with SPC vs. FC (-$208; 95% CI: -$302– -$114), but antihypertensive prescription costs were greater ($53; 95% CI: $51–$55).
### Bangalore S, et al., 2007 (313) 17679131

**Study type:** Meta-analysis to assess if compliance is improved with FDC therapy compared to free-drug regimens in chronic diseases including HTN, HIV, tuberculosis, and DM

**Size:** 9 studies total (n=20,242), 4 of which were in hypertensive populations (n=17,175)

**Inclusion criteria:**
- Database search of MEDLINE (1966–2005)
- Studies included if published in English and compared an FDC with free-drug combination of its components and reported medication compliance (adherence) or persistence

**1st endpoint:** Compliance, considered as either adherence or persistence to medication therapy

**Results:**
- Use of FDC therapy was associated with a 26% decreased risk of noncompliance vs. free-drug combinations (pooled RR: 0.74 (95% CI: 0.69, 0.80), p<0.0001) in all diseases states.
- There was no evidence of heterogeneity.
- In hypertensive pts, FDC was associated with 24% decreased risk of noncompliance (pooled RR: 0.76 (95% CI: 0.71, 0.81), p<0.0001) compared to free-drug regimen. There was no evidence of publication bias.
- Marked heterogeneity in how compliance was measured among studies

### Kumagai N, et al., 2013 (314) 23072348

**Study type:** Prospective, multicenter, observational study of pts converted from free-drug combinations of an ARB and amlodipine to the same product as a FDC.

**Size:** 196 pts

**Inclusion criteria:**
- Outpatients with essential HTN
- Self-measured home BP
- Prescribed FDC of an ARB (8 mg candesartan, 80 mg valsartan, or 40 mg telmisartan) and 5 mg and 5 mg amlodipine
- Pts divided into 2 groups: Group 1 received an ARB and amlodipine in the morning as free drug combinations and Group 2 took ARB in the morning and amlodipine in the evening. After 1 mo, both groups converted to once daily FDC product.

**Exclusion criteria:**
- Severe renal or liver dysfunction
- Severe HF
- Prescription of time-specific packs

**Endpoints:**
- Adherence to antihypertensive therapy as measured by self-reporting
- Self-monitored BP measurements and clinical BP measurements before and after switch to FDC antihypertensive therapy.
- Drug costs

**Results:**
- Self-monitoring BP measurements taken during early morning was lower with FDC compared to free-drug combinations (-5 mm Hg SBP, -2 mm Hg DBP; p<0.01 for both)
- Average clinic BP was lower with FDC compared to free-drug combination (-5 mm Hg SBP, -2 mm Hg SBP; p<0.01).
- Self-reported adherence was improved with FDC vs. free-combination agents (~99% vs. 95% p<0.01). SBP was significantly lower in the group with improved adherence (~7.5 mm Hg)

**Use of FDC combination therapy in hypertensive pts was associated with a 24% decreased risk of noncompliance compared to use of free-drug regimens.**

<tr>
<td>Mazzaglia G, et al., 2009 (315)</td>
<td>Retrospective cohort</td>
<td>18,046 pts</td>
<td>Newly diagnosed and treated hypertensive pts ≥35 y initially free of CVD identified from Italian general pt registry.</td>
<td>CHD, cerebrovascular disorders, congestive HF who had been hospitalized for CABG or coronary angioplasty, those recovered in a cardiology ward before index diagnosis, incident CV event in the 180 d after index diagnosis, pts receiving nitrates</td>
<td>Describe adherence to antihypertensive therapy and its associate with concurrent drug use, comorbidities, and CV risk factors. Adherence was estimated by calculating the proportion of days which pt had pills available during the follow-up.</td>
<td>At baseline (6 mo after index diagnosis), adherence rates were high (≥80% proportion of days covered) in 8.1% of pts, intermediate (40-79% proportion of d covered) in 4.5%, and low (≤40% proportion of d covered) in 51%. Multiple drug treatment (1.62; 95% CI: 1.43–1.83), dyslipidemia (1.52; 95% CI: 1.24–1.87), DM (1.40; 95% CI: 1.15–1.71), obesity (1.50; 95% CI: 1.26–1.78) and antihypertensive combination therapy (1.29; 95% CI: 1.15–1.45) were associated with high adherence to treatment (p&lt;0.001).</td>
</tr>
<tr>
<td>Jackson KC, et al., 2008 (316)</td>
<td>Retrospective cohort study</td>
<td>908 pts</td>
<td>• ≥18 y and diagnosis of HTN • Benefit-eligible for pharmacy claims • Antihypertensive naive (no prescription fill for antihypertensive drug ≥110 d prior to index date) • Received 1 of 3 regimens: 1.) 2 pill regimen with valsartan + amlodipine, 2.) 2-pill regimen with valsartan/HCTZ in FDC + amlodipine, 3.) 3-pill regimen with valsartan + HCTZ + amlodipine as free-drug components</td>
<td></td>
<td>Adherence as measured by MPR</td>
<td>Results: 224 pts received valsartan + amlodipine, 619 received valsartan/HCTZ + amlodipine, and 65 received valsartan + HCTZ + amlodipine. MPR ratios were 75.4% with valsartan + amloidipine, 73.1% with valsartan/HCTZ + amloidipine, and 60.5% with valsartan + HCTZ + amloidipine (p=0.005). Older age was associated with improved MPR (75.2% for those ≥64 y. vs. 69.6% for 18 to &lt;36 y; p=0.023).</td>
</tr>
</tbody>
</table>

• Healthcare costs were decreased by 31% per pt from 17,075 yen ($216.93 USD; Aug. 2012) to 11,815 yen ($150.10 USD; Aug. 2012) over the 3 mo period.

• High adherence was associated with a 38% decreased risk of CV events compared with low adherence. Combination therapy associated with 29% improved adherence compared to monotherapy.

• An inverse relationship existed between the number of pills and adjusted MPR, with lower adherence noted in 3-pill regimens vs. 2-pill regimens.
Exclusion criteria: Pts who received <2 prescription fills, did not continuously have prescriptions refilled for each medication, or switched from 1 medication to another without a time overlap.

Inclusion criteria:
- 65–100 y on index date
- Received at least 2 prescriptions for study drugs (amlodipine/benazepril FDC n=2336) or DHP-CCB and ACEI as separate agents [n=3368] between 1997–2001
- Continuously eligible for Medicaid for 12 mo following index date

1° endpoint: Determine rates of compliance (MPR) and total costs of care (defined as sum of payments for Medicaid claims for ambulatory care, hospital claims, prescription drug claims, and Medicare ross claims) in pts treated with FDC amlodipine/benazepril vs. a DHP-CCB and ACEI prescribed as free-combination agents.

Results: MPR was significantly higher for pts receiving FDC compared with free-combination therapy (63.5% vs. 49%; p<0.05). Average total cost of care (2002 value) was $3,179 with FDC compared to $5,236 with free-combination agents (p<0.0001). Multivariate regression analysis indicated an increase of 0.5% for each 1-unit increase in MPR, and for each comorbidity there was a 10.4% increase. Total cost of care for FDC group was 12.5% lower than free-combination group (p<0.003).

FDC combination therapy with amlodipine/benazepril was associated with better compliance than a DHP-CCB and ACEI as free-combination agents. FDC was also associated with lower total costs of care.

### Brownstein JN, et al., 2007 (320) 17478270

**Aim:** Examine the effectiveness of community health workers in supporting the care of pts with HTN

**Study type:** Systematic review

**Size:** 14 studies, including 8 RCTs

**Inclusion criteria:** Studies examining the effects of an intervention involving community health workers on the care of pts with HTN

**Exclusion criteria:** Studies that focused exclusively on outcomes among community health workers and those involving peers who merely led support groups

**Intervention:** Community health workers as HTN care team members. Community health workers were broadly defined as health workers who were trained as part of an intervention, had no formal paraprofessional designation, and had a relationship with the community being served. The community health workers, predominantly women, were recruited from the community, and resembled the pts in race/ethnicity and socioeconomic background. Roles included: (1) providing health education and information to pts and families; (2) ensuring that pts received services necessary for BP control; (3) providing direct services, including measuring and monitoring BP; (4) providing social support to the pts and their family members; and (5) serving as mediators between pts and the healthcare and social service systems.

**Comparator:** Usual care or other comparison group

**1° endpoint:** Differences between groups in BP control groups favored community health worker groups over control and ranged from 4%-46% over 6–24 mo, across 7 RCTs; though 1 RCT showed no difference between groups.

**Safety endpoint:** N/A

**2° endpoints:**
- Appointment keeping: significant improvements ranging from 19%-39% (relative changes) over 12–24 mo in community health worker intervention
- Adherence to medications: Range of findings included significant improvement in community health worker intervention group compared with control, between-group differences ranged from 8%-14%; 26% greater compliance among pts receiving intense community health worker interventions; and 17% significant improvement in adherence to medication with counseling by community health workers.

**Limitations:** High level of heterogeneity of the populations, settings, interventions, and outcomes

**Summary:** Including community health workers as part of the HTN care team resulted in significant improvements BP control, appointment keeping, and adherence to antihypertensive medications, primarily among low income, urban African Americans.

| Shaw RJ, et al., 2014 (325) 25023250 | **Aim:** Determine whether nurse-managed protocols are effective for outpatient management of pts with DM, HTN, and hyperlipidemia (HTN RCT outcomes only included here)  
**Study type:** Meta-analysis  
**Size:** 12 RCTs, with 10,362 pts, of nurse-managed protocols for outpatient management of HTN  
**Inclusion criteria:** RCT of nurse-managed protocols for outpatient management of HTN  
**Exclusion criteria:** Absence of above  
**Intervention:** Involvement of a registered nurse or a licensed practical nurse functioning beyond the usual scope of practice, such as adjusting medications and conducting interventions based on a written protocol. All studies used a nurse who titrated medications by following a protocol.  
**Comparator:** Usual care | **1° endpoint:**  
- SBP and DBP decreased by 3.68 mm Hg (95% CI: 1.05–6.31 mm Hg) and 1.56 mm Hg (95% CI: 0.36–2.76 mm Hg), respectively, with high variability (I²>70%)  
- Nurse-managed protocols were more likely to achieve target BP than control protocols (OR: 1.41; 95% CI: 0.98–2.02), though difference was not significant and treatment effects were highly variable (Q 35.20; I²=74%).  
**2° endpoints:**  
- Included studies of low/good quality as well as moderate/fair, and high quality  
- Descriptions of interventions and protocols were limited  
| Nurse-managed protocols for HTN care were associated with a mean decrease in SBP and DBP but not increase in HTN control. |
| Carter BL, et al., 2015 (326) 25805647 | **Aim:** Evaluate if a physician/pharmacist collaborative model would be implemented as determined by improved BP control and whether long-term BP control could be sustained  
**Study type:** Cluster RCT  
**Size:** 32 primary care offices from 15 states enrolled 625 pts with uncontrolled HTN; 54% from racial/ethnic minority groups and 50% with DM or CKD  
**Inclusion criteria:** Offices were required to have an onsite clinical pharmacist must have practiced in the office. Pts were eligible if they were English or Spanish speaking, ≥18 y with uncontrolled BP as measured by the SC on the baseline visit.  
**Exclusion criteria:** Absence of above  
**Intervention:** Pharmacist conducted medical record review and a structured interview with the subject, including 1) a medication history; 2) an assessment of knowledge of BP medications, dosages and timing, and potential side effects; and 3) other barriers to BP control (e.g., side effects and nonadherence). The model recommended a telephone call at 2 wk, structured face-to-face visits at baseline, 1, 2, 4, 6, and 8 mo and additional visits if BP remained uncontrolled. The pharmacist created a care plan with recommendations for the physician to adjust  
**Comparator:** Usual care  
**1° endpoint:** BP control at 9 mo was 43% in intervention offices compared with 34% in control group (adjusted OR: 1.57 (95% CI: 0.99, 2.50), p=0.059).  
**Safety endpoint:** N/A  
**2° endpoints:**  
- The adjusted difference in mean SBP/DBP between the intervention and control groups for all pts at 9 mo was −6.1/−2.9 mm Hg (p=0.002 / p=0.005, respectively), and it was −6.4/−2.9 mm Hg (p=0.009 / p=0.044, respectively) in pts from racial or ethnic minorities.  
- BP control and mean BP were significantly improved in pts from racial minorities in intervention offices at 18 and 24 mo (p=0.048 and p<0.001) compared with the control group.  
**Summary:** Although the results of the 1° outcome (BP control) were negative, the key 2° endpoint (mean BP) was significantly improved in the intervention group. Thus, the findings for 2° endpoints suggest that team-based care using clinical pharmacists significantly
therapy based on the JNC-7, and the BP goals were <140/90 mm Hg for uncomplicated HTN or <130/80 mm Hg for pts with DM or CKD. The pharmacists did not follow algorithms or protocols other than JNC-7. Physicians were free to accept or to reject any recommendation or to modify the plan. Recommendations to pts focused on medication education, improving adherence, and strategies to implement lifestyle modifications.

**Comparator:** Pharmacists in control offices were instructed to avoid intervention for study pts with HTN, but they could provide usual care curbside consultations if physicians specifically asked questions.

**Comparator:** Pharmacists in control offices were instructed to avoid intervention for study pts with HTN, but they could provide usual care curbside consultations if physicians specifically asked questions.

Factors associated with HTN diagnosis were assessed through multivariate analyses of pt clinical and demographic characteristics. Predictors of ABP readings. Predictors for incident HTN diagnosis were similar. In pts with 2 or more abnormal BP readings, HTN diagnosis was associated with significantly higher medication treatment rates (92.6% vs. 15.8%; p<0.0001).

### Jaffe MG, et al., 2013 (329) 23989679

**Aim:** Study the effect of a multipronged, system-based, QI approach on HTN control.

**Study type:** Observational

**Size:** All pts with HTN in the KPNC system were included

**Inclusion criteria:**
- 350,000 pts in the KPNC system with HTN in 2001, increasing to 650,000 in 2009
- ≥2 HTN diagnoses coded in primary care visits in the prior 2 y
- ≥1 primary care HTN diagnoses and 1 or more hospitalizations with a 1º or 2º HTN diagnosis in the prior 2 y
- ≥1 primary care HTN diagnoses and 1 or more filled prescriptions for HTN medication within the prior 6 mo, or
- ≥1 primary care HTN diagnoses and 1 or more stroke-related hospitalizations or a history of coronary disease, HF, or DM

**Intervention:** KPNC HTN Program includes:
- HTN registry.
- HTN control monitoring and feedback system.
- Evidence-based practice guidelines.
- Medical assistant BP recheck program.
- Promotion of single polypill formulation (lisinopril-hydrochlorothiazide)

**Comparator:** Insured pts in California from 2006–2009 who were included in the HEDIS commercial measurement by California health insurance plans participating in the NCQA quality measure reporting process. A 2º comparison group was included to obtain the reported national mean NCQA HEDIS commercial rates of HTN control.

**1º endpoint:**
- HTN control rates in KPNC pts with HTN improved from 43.6% (95% CI: 39.4%, 48.6%) in 2001 to 80.4% (95% CI: 75.6%, 84.4%) by the end of the study period (p<0.001 for trend).
- By comparison, national mean NCQA HEDIS commercial measurement HTN control increased from 55.4%–64.1%.
- California mean NCQA HEDIS commercial rates of HTN control were similar to those reported nationally from 2006–2009 (63.4%–69.4%).

**1º Safety endpoint:** N/A

• A system-based approach to HTN control that includes performance measurement and QI strategies led to a significant improvement in HTN control (80%, compared to 44% baseline control) in a large population of pts in a managed care health plan.
**Aim:** The goal of this study was to develop a technology-based strategy to identify pts with undiagnosed HTN in 23 primary care practices and integrate this innovation into a continuous QI initiative in a large, integrated health system.

- Of the 139,666 active adult primary care pts in these 23 practices, 47,822 already had a diagnosis of HTN, white-coat HTN, pre-HTN, or elevated BP. The 3 screening algorithms for undiagnosed HTN were applied to the remaining pts' EHRs. There were 1,586 pts who met the criteria of 1 or more of the algorithms and were therefore considered at risk for undiagnosed HTN.

- In phase 1, we reviewed EHRs using algorithms designed to identify pts at risk for undiagnosed HTN. We then invited each at-risk pt to complete an automated office BP protocol. In phase 2, we instituted a QI process that included regular physician feedback and office-based computer alerts to evaluate at-risk pts not screened in phase 1. Study pts were observed for 24 additional mo to determine rates of diagnostic resolution. After phase 1, we established a continuous QI initiative to further evaluate pts who remained at risk for undiagnosed HTN. In this 24-mo follow-up phase (phase 2), all primary care physicians received monthly lists of their pts who continued to be at risk for undiagnosed HTN.

- Of the 1,033 at-risk pts who remained active during phase 2, 740 (72%) were classified by the end of the follow-up period: 361 had HTN diagnosed, 290 had either white coat HTN, pre-HTN, or elevated BP diagnosed, and 89 had normal BP. By the end of the follow-up period, 293 pts (28%) had not been classified and remained at risk for undiagnosed HTN.

- Although we used multiple algorithms to identify pts with elevated BP readings, it is unlikely that we identified all pts with undiagnosed HTN.
These pts were contacted by staff via telephone or letter to arrange a follow-up appointment. These pts remained on the physicians' lists until an automated office BP evaluation was completed or an ICD-9 diagnosis was entered into the chart that indicated the pt's at-risk status had been resolved. In addition, when an at-risk pt arrived for an office visit for any reason, a best practice advisory was prominently displayed on that pt's EHR screen to notify the medical assistant and physician that an automated office BP measurement was needed.

Borden WB, et al., 2014 (331) 25447261

**Aim:** The purpose of this study was to examine the effect of the 2014 expert panel BP management recommendations on pts managed in U.S. ambulatory CV practices.

- Using the National CV Data Registry PINNACLE Registry, we assessed the proportion of 1,185,253 pts who met the 2003 and 2014 panel recommendations, highlighting the populations of pts for whom the BP goals changed.

N/A

- Of 1,185,253 pts in the study cohort, 706,859 (59.6%) achieved the 2003 JNC-7 goals. Using the 2014 recommendations, 880,378 (74.3%) pts were at goal. Among the 173,519 (14.6%) for whom goal achievement changed, 40,323 (23.2%) had a prior stroke or TIA, and 112,174 (64.6%) had CAD. In addition, the average Framingham risk score in

- Among U.S. ambulatory cardiology pts with HTN, nearly 1 in 7 who did not meet JNC-7 recommendations would now meet the 2014 treatment goals.
Data Supplement 64. RCTs, Meta-analyses, and Systematic Reviews on the Effect of Telehealth Interventions to Improve Hypertension Control (Section 12.3.2)

</tr>
</tbody>
</table>

**Summary:** HBPT yielded greater SBP and DBP reductions and a larger proportion of pts achieving BP control than usual care. HBPT vs. usual care resulted in greater prescription of antihypertensive medications and fewer office visits but no difference in therapeutic adherence. Healthcare costs were higher with HBPT than usual care, but when HBPT-related costs were excluded, medical costs were similar between groups. Use of HBPT vs. usual care improved quality of life physical component but not mental. Authors note that the amount of office BP reduction attributable to HBPT was in line with that observed in RCTs of antihypertensive drugs compared with placebo. The estimate was also larger than that usually related to HBP self-monitoring, which speaks in favor of a possible added value of the teletransmission approach.
| Verberk W, et al., 2011 (335) 21527847 | **Aim:** Examine the usefulness of telecare for HTN management |
| Study type: Meta-analysis |
| **Size:** 9 RCTs with 2,501 pts |
| **Inclusion criteria:** 1) Published in the English language, 2) pts were diagnosed as hypertensive and performed BP self-measurement at home, 3) RCTs that compared telecare of BP with usual care, 4) data were transmitted to healthcare providers by telephone, modem, Internet, or mail, and 5) either change in BP or the number of pts that reached their target BP was an outcome and was provided in the study. Date restrictions not reported. |
| **Exclusion criteria:** Absence of above |
| **Intervention:** Telecare for HTN management (treatment and/or coaching). Telecare involved a data transmission process to collect data on a pt's health status to allow remote HTN management. Procedures varied in length and frequency of contact and method of delivery (i.e., often telephone or cell phone with or without internet/computer; with or without behavioral counseling by nurse or pharmacist), often as an adjunct to "usual care" clinical visits. |
| **Comparator:** Usual care |
| **1º endpoint:** Difference in BP Reduction (Telecare-Usual care):  
  • SBP 5.2 ± 1.5 mm Hg (95% CI: 2.31–8.07)  
  • DBP 2.1 ± 0.8 mm Hg (95% CI: 0.52–3.69) |
| **Safety endpoint:** N/A |
| **Limitations:** Telecare intervention methods varied greatly across studies |
| **Summary:** Telecare led to a greater decrease in SBP and DBP compared with usual care. Telecare seems a valuable tool to support HTN management. |
### Aim:
Quantify both the magnitude and mechanisms of benefit (including effect on therapeutic inertia) of home BP monitoring on BP reduction. Therapeutic inertia was defined as no change in medications combined with uncontrolled BP.

**Study type:** Systematic review and meta-analysis

**Size:** 37 RCTs with 9,446 pts. Trial settings included community (n=5), dialysis unit (n=2), general practices (n=18), hospitals and general practice (n=1), and hospital-based outpatient units (n=11).

### Inclusion criteria:
Studies that randomized pts to control or home BP monitoring group

### Exclusion criteria:
Absence of above

### Intervention:
Home BP monitoring as an adjunct to usual care for HTN

### Comparator:
Usual care with BP monitoring in clinic

### 1° endpoint:
Compared with usual care alone, home-based BP monitoring:
- Reduced SBP: -2.63 mm Hg (95% CI: -4.24 – -1.02) and
- Reduced DBP: -1.68 mm Hg (95% CI: -2.58– -0.79)

Greater reduction in SBP by HBPM interventions was seen with added telemonitoring (effect size -3.20; 95% CI: -4.66– -1.73) vs. home BP monitoring (effect size -1.26; 95% CI: -2.20– -0.31; p=0.029). This finding is relevant to telemonitoring

### 2° endpoints:
- More frequent reductions in antihypertensive medication (presumably due to identification of white coat HTN): RR: 2.02 (95% CI: 1.32–3.11)
- Lowered therapeutic inertia (i.e., unchanged medication despite elevated BP: RR for unchanged medication 0.82 (95% CI: 0.68–0.99)

### Limitations:
Different inclusion and exclusion criteria, different BP measurement techniques, drug titration protocols, pt populations, and duration of follow-up across studies likely introduced significant heterogeneity in effect size.

### Summary:
Home BP monitoring leads to a small but significant reduction in SBP and DBP. Greater reduction in SBP is seen when HBPM is accompanied by specific programs to titrate antihypertensive drugs. 1 such strategy is telemonitoring, in which BP readings obtained at home are relayed to the provider who can then take appropriate action, thus reducing therapeutic inertia.

---

| | **Study type:** Observational |
| | **Size:** All pts with HTN in the KPNC system were included |
| | **Inclusion criteria:** 350,000 pts in the KPNC system with HTN in 2001, increasing to 650,000 in 2009 |
| | **Eligibility:** ≥2 HTN diagnoses coded in primary care visits in the prior 2 y ≥1 primary care HTN diagnoses and 1 or more hospitalizations with a 1° or 2° HTN diagnosis in the prior 2 y ≥1 primary care HTN diagnoses and 1 or more filled prescriptions for HTN medication within the prior 6 mo, or |
| | **Intervention:** KPNC HTN Program includes: HTN registry, HTN control monitoring and feedback system, evidence-based practice guidelines, medical assistant BP recheck program, and promotion of single polypill formulation (lisinopril-hydrochlorothiazide) |
| | **Comparator:** Insured pts in California from 2006–2009 who were included in the HEDIS commercial measurement by California health insurance plans participating in the NCQA quality measure reporting process. A 2° comparison group was included to obtain the reported national mean NCQA HEDIS commercial rates of HTN control from 2001– |
| | **1° endpoint:** HTN control rates in KPNC pts with HTN improved from 43.6% (95% CI: 39.4%–48.6%) in 2001 to 80.4% (95% CI: 75.6%–84.4%) by the end of the study period (p<0.001 for trend). By comparison, national mean NCQA HEDIS commercial rates of HTN control were similar to those reported nationally from 2006–2009 (63.4%–69.4%). |
| | **A system-based approach to HTN control that includes performance measurement and QI strategies led to a significant improvement in HTN control (80%, compared to 44% baseline control) in a large population of pts in a managed care health plan.** |
### Lusignan Sd, et al., 2013 (337) 23536132

**Aim:** Study the effect of an audit-based education intervention to guidelines/prompts, vs. usual care, to help improve BP control in pts with CKD

**Study type:** Cluster RCT

**Size:** 93 general practices (30 audit-based education intervention, 32 Guidelines/prompts, and 31 usual care)

**Inclusion criteria:** All pts with CKD in the participating practices

**Intervention:** Audit-based education vs. guidelines/prompts

**Comparator:** Usual care

**1° endpoint:** SBP was significantly lower in the audit-based education group (-2.41 mm Hg; 95% CI: 0.59–4.29). There was no significant change in BP in the other 2 groups.

**1° Safety endpoint:** No reports of harm.

- This trial suggests that an intervention that includes specific performance and feedback reports improves BP control in pts with CKD, compared to usual care. To the contrary, the use of practice guidelines and prompts did not improve BP control compared to usual care.

| Agarwal R, et al., 2011 (27) | **Aim:** Quantify both the magnitude and mechanisms of benefit (including effect on therapeutic inertia) of home BP monitoring on BP reduction. Therapeutic inertia was defined as no change in medications combined with uncontrolled BP. | **Inclusion criteria:** Studies that randomized pts to control or home BP monitoring group | **Intervention:** Home BP monitoring as an adjunct to usual care for HTN | **1° endpoint:** Compared with usual care alone, home-based BP monitoring:  
- Reduced SBP: -2.63 mm Hg (95% CI: -4.24-- -1.02) and  
- Reduced DBP: -1.68 mm Hg (95% CI: -2.58-- -0.79)  
- Greater reduction in SBP by home BP monitoring interventions was seen with added telemonitoring effect size: -3.20 (95% CI: -4.66-- -1.73) vs. home BP monitoring effect size: -1.26; 95% CI: -2.20-- -0.31; p=0.029. | **Safety endpoint:** N/A  
**2° endpoints:**  
- More frequent reductions in antihypertensive medication (presumably due to identification of white coat HTN): RR: 2.02; 95% CI: 1.32–3.11  
- Lowered therapeutic inertia (i.e., unchanged medication despite elevated BP: RR for unchanged medication 0.82 (95% CI: 0.68–0.99) | **Exclusion criteria:** Absence of above | **Comparator:** Usual care with BP monitoring in clinic | **Algorithm:** (-8.46 mm Hg; p<0.001), completion of a drug profile and/or medication history (-8.28 mm Hg; p=0.001), and the overall intervention potency score assigned by the study reviewers (p=0.001). The factors associated with a reduction in DBP were: referral was made to a specialist (-19.61 mm Hg; p=0.04), providing pt education about BP medications (-17.60 mm Hg; p=0.003), completion of a drug profile and/or medication history (-7.27 mm Hg; p=0.006), pharmacist performed the intervention (-4.03 mm Hg; p=0.04), or nurse performed the intervention (-3.94 mm Hg; p=0.04). | **Summary:** Interventions involving pharmacists or nurses were associated with significantly improved BP control. | **Study type:** Systematic Review and Meta-analysis |

**Anchala R, et al., 2012 (339) 23071713**

**Aim:** Evaluate the role of decision support systems in prevention of CVD among pts

**Study type:** Systematic review and meta-analysis

**Size:** 10 studies with 5 studies reporting effect on BP (BP results only reported here)

**Inclusion criteria:** 1) Cross-sectional, case control, cohort, and RCTs, 2) Studies conducted among adult pts ≥18, 3) studies on prevention of CV disorders (MI, stroke, CHD, peripheral vascular disorders and HF) and management of HTN, 4) studies on interventions including: decision support systems, clinical decision support systems, computerized decision support systems, clinical decision making tools and medical decision making

**Exclusion criteria:** Absence of above

**Intervention:** Decision support systems, clinical decision supports systems, computerized decision support systems, clinical decision making tools and medical decision making

**Comparator:** Usual care

**1° endpoint:**
- Reduction in SBP (5 studies): 2.32 mm Hg (95% CI: -3.96--0.69)
- Reduction in DBP (2 studies): 0.42 mm Hg (95% CI: -2.30–1.47)

**Safety endpoint:** N/A

**Limitations:**
- Small number of studies of varied quality.
- Interventions varied across studies.

**Summary:** Clinical decision support resulted in modest reduction of SBP and no significant reduction of DBP.

**Proia KK, et al., 2014 (323) 24933494**

**Aim:** Examine current evidence on the effectiveness of team-based care in improving BP outcomes (update of

**Inclusion criteria:** Study of team-based care; conducted in a high-income economy; reported at least 1 BP outcome of interest; included a comparison group or had

**Intervention:** Team-based care was defined as adding new staff or changing the roles of existing staff to work with a PCP for HTN care. Team members who

**Comparator:** Usual care

**1° endpoint:**
- Proportion with controlled BP: Absolute percentage point (pct pt) change in pts with controlled BP from 33 studies comparing team-based care to usual care: median effect

**2° endpoints:** Compared with pts in usual care, the proportion of pts receiving team-based care with "high" medication adherence (defined as taking medications as prescribed >80% of the time) increased by a median of 16.3 pct pts (9 studies).
Study type: Systematic review

Size: 52 studies of team-based primary care for pts with 1° HTN

Exclusion criteria: Inclusion of populations with 2º HTN (e.g., pregnancy) or with a history of CVD (e.g., MI)

Key roles included HTN medication management, active pt follow-up, and adherence and self-management support. Interventions were usually implemented across multiple settings in the healthcare system and in the community, where they were implemented in pharmacies and through home outreach visits.

Comparator: Usual care estimate was 12 pct pts (IQI=3.2–20.8 pct pts). Most individual effect estimates in the favorable direction were significant (p<0.05).

Reduction in SBP (44 studies): The median reduction in SBP was 5.4 mm Hg (IQI=2.0–7.2 mm Hg). Most individual effect estimates were significant (p<0.05).

Reduction in DBP: The overall median reduction in DBP was 1.8 mm Hg (IQI=0.7–3.2 mm Hg) from 38 studies.

Safety endpoint: No harm to pts was identified from team-based care interventions in the included studies or the broader literature.

Stratified analyses for BP outcomes:

- Team member role in medication management: Larger improvements in BP outcomes than overall estimates were demonstrated when team members could make changes to medications independent of the PCP or team members could provide medication recommendations and make changes with the PCP's approval as compared to team members providing only adherence support and information on medication and HTN.

- Number of team members added: Adding ≥2 members demonstrated larger improvements in the proportion of pts with controlled BP and reduction in DBP compared to adding only 1; median reductions in SBP were similar regardless of team size.

- Improvement in the proportion of pts with controlled BP was similar for studies from both healthcare and community settings.

Limitations: Included studies reported significant differences in pt demographics between intervention and comparison groups at baseline, possible contamination within intervention and comparison groups, and issues related to inadequate description of populations and implemented interventions.

Summary: There is strong evidence that team-based care is effective in
improving BP outcomes, especially when pharmacists and nurses are part of the team.

| Thomas KL, et al., 2014 (340) 25351480 | **Study type:** Community-based HTN QI program [multifaceted BP control program using a web-based health portal (Heart360), community health coaches, and PA guidance] to improve HTN control in a diverse community setting  
**Design:** Pre-post study without a concurrent control  
**Size:** 1756 pts with HTN from 8 clinics:  
- Median age, 60 y  
- Female, 65.6%  
- African American, 76.1%  
**Inclusion criteria:** Individuals from pt sites >18 y with a previous billing diagnosis of HTN (ICD-9 code 401.X) or a previous clinical diagnosis of HTN in the medical record.  
**Exclusion criteria:** Did not reside in Durham County or had a neurocognitive disorder that prevented enrollment | 1° endpoint: 1) Difference in SBP and DBP from enrollment (BP obtained in the clinic at enrollment) to the last BP as measured in clinic within 6 mo after enrollment, 2) proportion of pts that achieved BP <140/90 mm Hg by last clinic visit within 6 mo, and 3) proportion of pts with BP <140/90 mm Hg or drop in SBP ≥10 mm Hg by last visit relative to their enrollment BP.  
Results:  
- Mean change in BP: -4.7 mm Hg (SD ± 21.4) / -2.8 mm Hg (SD ± 11.8) after 6 mo  
- BP control (<140/90 mm Hg) rate: Increased from 51% at baseline to 63% at 6 mo  
- Proportion with BP<140/90 or ≥10 mm Hg decrease in SBP at 6 mo was 69%  
- Among those who were in tiers 1 (BP=140/90–159/99 mm Hg) and 2 (BP≥159/99 mm Hg) at enrollment (n=889), BP change was -8.8 mm Hg (SD ± 15.8) / -5.0 mm Hg (SD ± 10.0) and -23.7 mm Hg (SD ± 26.5) / -10.1 mm Hg (SD ± 14.1), respectively. | **Summary:** A multicomponent-tiered HTN program that included team-based care with PAs and community health coaches was associated with improved BP control in a diverse community-based population. Though the web-based approach presented technical challenges for some pts, there was a direct association between higher use of Heart360 and larger recorded BP declines as entered into Heart360. This provides some indirect evidence that those pts who were more engaged with their BP self-monitoring achieved better BP control. |

| Jaffe MG, et al., 2013 (329) 23999679 | **Study type:** Quasi-experimental evaluation of multi-faceted QI program that included 1) Health system-wide HTN registry, 2) HTN control rates (with provider audit and feedback), 3) | 1° endpoint: BP control using NCQA HEDIS measures  
**Results:** BP control increased from 44%–80% from 2001–2009 with the KPNC QI program compared to 55.4% to 64.1% for the national mean and 63.4% to 67.3% for the state mean. | **Summary:** Implementation of a large-scale HTN program was associated with a significant increase in HTN control compared with state and national control rates. |
Evidence-based practice HTN guideline, 4) medical assistant visits for follow-up measurements with no pt copayment for these follow-up visits, and 5) promotion of single-pill combination therapy.

**Design:** Contemporaneous control group external to healthcare system

**Size:** Kaiser HTN registry increased from 349,937 pts in 2001 to 652,763 in 2009.

**Exclusion criteria:** None stated

69.4% for the Ca mean from 2006 to 2009 NCQA HEDIS commercial measurement comparison groups.

<td>Peterson LA, et al., 2013 (341) 24026599</td>
<td><strong>Aim:</strong> To test the effect of explicit financial incentives to reward guideline recommended HTN care. <strong>Study type:</strong> Cluster randomized trial of 12 VA Outpatient clinics with 5 performance periods and a 12-mo washout <strong>Size:</strong> 83 PCPs and 42 nonphysician</td>
<td>• Study population was providers, not pts: a minimum of 5 fulltime PCPs from 12 hospital-based primary care clinics in 5 A Networks. Then, the clinics were randomized to 1 of 4 study groups, 1) physician level (individual) incentives, 2) practice-level incentives, 3) physician-level plus practice-level (combined) incentives, and 4) no incentives (control).</td>
<td><strong>Interventions:</strong> Education, Financial Incentives, Audit and Feedback; Intervention group pts received up to 5 incentive payments in their paychecks every 4 mo and were notified each time a payment was posted. <strong>Comparator:</strong> 4 different groups, 1 paid incentives at the practice level, 1 paid incentives at the physician level, 1 paid incentives and 1 no incentives</td>
<td><strong>1st endpoint:</strong> In unadjusted analyses, the percentage of pts either with controlled HTN or receiving an appropriate response increased for each incentive group between baseline and final performance period, 75% to 84% in the individual group, 80% to 85% in the practice group, and 79% to 88% in the combined group. Performance did not change in control group, 86%. The adjusted estimated ab-solute change over the study of the pts meeting the combined BP or</td>
<td><strong>Summary:</strong> • Mean (SD) total payments over the study were $4,270 ($459), $2672 ($153), and $1,648 ($248) for the combined, individual, and practice-level interventions, respectively. Change in BP control or appropriate response to uncontrolled BP compared with the control group was significantly greater only in the individual incentives group. Change in guideline-recommended medication use was not significant compared with the control group. The effect of the incentive was not sustained after a washout.</td>
</tr>
</tbody>
</table>
Main Outcomes and Measures: Among a random sample, number of pts achieving guideline-recommended BP thresholds or receiving an appropriate response to uncontrolled BP, number of pts prescribed guideline-recommended medications, and number who developed hypotension.

Karunaratne K, et al., 2013 (343) 23658247

**Aim:** The aim of this study was to evaluate the effectiveness of renal indicators outlined in P4P on the management of HTN in primary care. To estimate the cost implications of the resulting changes in prescribing patterns of antihypertensive medication following introduction of such indicators.

**Study type:** Prospective cohort study using a large primary care database.

**Inclusion criteria:** A total of 10,040 pts had confirmed stage 3–5 CKD in the 2 y pre-QOF and formed the study cohort.

**Exclusion criteria:** None

**Intervention:** The implementation of national estimated GFR reporting and the inclusion of renal-specific indicators in a primary care P4P system since April 2006 has promoted identification and better management of risk factors related to CKD. In the UK, the P4P framework is known as the QOF.

**Comparator:** N/A

**Safety endpoint:** N/A

Mean age of the cohort at the start of the study period was 64.8 y, 55% were female. In those pts with stage 3–5 CKD 83.9% were hypertensive, defined by a pre-P4P BP of >140/85 or currently taking antihypertensive medication. The proportion of pts with CKD 3–5 attaining the BP target of 145/80 increased from 41.5% in the pre-QOF period to 50.0% in the post-QOF period. This increase was even more marked for those with HTN in the pre-QOF period (28.8%–45.1%). In the hypertensive pts, mean BP fell from 146/79 mm Hg to 140/76 in the first 2 y post-P4P [p<0.01, analysis of variance].

Summary: Population BP control has improved since the introduction of P4P renal indicators, and this improvement has been sustained. This was associated with a significant increase in the use of antihypertensive medication, resulting in increased prescription cost. Longer-term follow-up will establish whether or not this translates to improved outcomes in terms of progression of CKD, CVD and pt mortality.

Financial incentives may constitute an insufficiently strong intervention to influence goal commitment when providers attribute performance to external forces beyond their control.
This cohort was taken from a database collated as part of a clinical decision support system used to assist the management of CKD in primary care.

**Size:** 90,250 pts on general practitioner registers with a valid serum creatinine estimation in the 6-y study period. A total of 10,040 pts had confirmed stage 3–5 CKD in the 2 y pre-QOF and formed the study cohort.

BP reduction was sustained in the last 2 y of the study, 139/75 (p<0.01, analysis of variance). The proportion of hypertensive pts taking ACEIs or angiotensin blockers increased, this was also sustained in the third time period. An increase in the prescribing of diuretics, CCBs and BBs was also observed. The additional cost of increased prescribing was calculated to be euro 25.00 per hypertensive pt based on GP prescription data.

| Aim | The aim of this study was to evaluate the effectiveness of renal indicators outlined in P4P on the management of HTN in primary care. To estimate the cost implications of the resulting changes in prescribing patterns of antihypertensive medication following introduction of such indicators. |
| Study type: interrupted time series study |
| Exclusion criteria: None |
| Intervention: The UK P4P incentive (the Quality and Outcomes Framework), which was implemented in April 2004 and included specific targets for general practitioners to show high quality care for pts with HTN (and other diseases). |
| Comparator: None |
| Summary: Good quality of care for HTN was stable or improving before P4P was introduced. P4P had no discernible effects on processes of care or on HTN related clinical outcomes. Generous financial incentives, as designed in the UK P4P policy, may not be sufficient to improve quality of care and outcomes for HTN and other common chronic conditions. |
| **Size:** 470,725 pts with HTN diagnosed between Jan 2000–Aug 2007. | **Aim:** To assess the effect of P4P incentives on quality in EHR-enabled small practices in the context of an established QI initiative. **Study Type & Size:** A cluster-randomized trial of small (<10 clinicians) primary care clinics in New York City from April 2009–March 2010. | **Participating clinics (n=42 for each group) had similar baseline characteristics, with a mean of 4,592 (median, 2,500) pts at the intervention group clinics and 3,042 (median, 2,000) at the control group clinics.** **A city program provided all participating clinics with the same EHR software with decision support and pt registry functionalities and QI specialists offering technical assistance.** **Incentivized clinics were paid for each pt whose care met the performance criteria, but they received higher payments for pts with comorbidities, who had Medicaid insurance, or who were uninsured (maximum payments: $200/pt; 100,000/clinic).** | **Intervention clinics had greater adjusted absolute improvement in rates of appropriate antithrombotic prescription 12.0% vs. 6.1%, difference: 6.0% (95% CI: 2.2%–9.7%; p=0.001 for interaction term), BP control (no comorbidities): 9.7% vs. 4.3%, difference: 5.5% (95% CI: 1.6%–9.3%; p=0.01 for interaction term); with DM: 9.0% vs. 1.2%, difference: 7.8% (95% CI: 3.2%–12.4%; p=0.007 for interaction term); with DM or ischemic vascular disease: 9.5% vs. 1.7%, difference: 7.8% (95% CI: 3.0%–2.6%; p=0.01 for interaction term), and in smoking cessation interventions (12.4% vs. 7.7%, difference: 4.7% (95% CI: −0.3%–9.6%; p=0.02 for interaction term).** | **Summary:** In our study, although the effect of the intervention was lower than the 10% improvement that we estimated a priori, the absolute risk reduction for BP control among pts with DM was 7.8% (NNT, 13). This suggests that, for every 13 pts seeing incentivized clinicians, 1 more pt would achieve BP control. The 7.8% absolute change in BP control for pts with DM represents a 46% relative increase in BP control among intervention pts compared with the baseline of 16.8%. Further research is needed to determine whether this effect of the P4P intervention on BP control increases or decreases over time. However, this NNT to achieve BP control through incentives, taken together with the large relative increase in percentage of pts with BP control and the potential effect of BP control on risk of ischemic vascular events, suggests a reasonable opportunity to reduce morbidity and mortality through P4P as structured in this study. | **Limitations:** Some clinics exited the program after randomization, with more control clinics leaving than intervention clinics. Additionally, this intervention occurred in the setting of a voluntary QI program. This may reflect a high level of intrinsic

</table>
countries, and 1 in a low-income country. Studies reported associations between increased medication costs or co-payments and reductions in HTN control or reduced adherence to antihypertensive medication, although for 1 of these 7 cohort studies, the association between increased copayments and reduced medication adherence was only found for low medication co-payments, and at high co-payment levels medication adherence was actually found to increase (OR for medication adherence vs. baseline of 1 for $0 co-payments was 0.72 for $1–$9 co-payments (p=0.05), 1.02 for $10–$29 co-payments (p=0.05), and 1.32 for co-payments ≥$30 (p=0.05).

• Physician remuneration models: 2 studies evaluated the association of physician remuneration models with HTN control or treatment adherence, 1 an ecological study set in Canada, and 1 a U.S. cross-sectional study. Neither study had a low risk of bias. The U.S. study reported improved rates of HTN control amongst pts treated under a capitation model compared to fee-for-service pts (adjusted OR for HTN control: 1.82 (95% CI: 1.02–3.27) for capitation vs. fee-for-service pts). The Canadian study reported highest rates of HTN
| treatment and control among practices using a capitation model, compared to fee-for-service and salary model. HTN awareness levels were highest in practices with a fixed salary remuneration model. |
Colors correspond to COR in Table 1. For all medical therapies dosing should be optimized and serial assessment exercised.

*See text for important treatment directions.

†Hydral-Nitrates Green Box- The combination of ISDN/HYD with ARNI has not been robustly tested. BP response should be carefully followed.

‡See 2013 HF guideline.

§Participation in investigational studies is also appropriate for stage C, NYHA class II and III HF.

ACEI indicates angiotensin-converting enzyme inhibitor; ARB, angiotensin receptor blocker; ARNI, angiotensin receptor-neprilysin inhibitor; BP, blood pressure; bpm, beats per minute; C/I, contraindication; CRT-D, cardiac resynchronization therapy-device; COR, class of recommendation; Dx, diagnosis; GDMT, guideline-directed management and therapy; HFrEF, heart failure with reduced ejection fraction; ICD, implantable cardioverter-defibrillator; ISDN/HYD, isosorbide dinitrate hydral-nitrates; LBBB, left bundle-branch block; LVEF, left ventricular ejection fraction.
Data Supplement B. Medication Adherence Assessment Scales

**Data Supplement E. Examples of Hypertension Quality Improvement Strategies**

<table>
<thead>
<tr>
<th>Quality Improvement Strategy</th>
<th>Examples</th>
</tr>
</thead>
</table>
| Audit and feedback on performance | • Feedback of performance to individual providers  
• Benchmarking – provision of outcomes data from top performers for comparison with provider’s own data  
• Performance measures, quality indicators and reports  
• Use of registries to track BP control status at system and provider levels |
| Provider education | • In person, online, or other education to improve BP measurement and management skills  
• Training to improve communication, cultural competency, and ability to inspire and support lifestyle modification |
| Patient education | • Intensive education strategies promoting hypertension self-management  
• Cultural and linguistic tailoring of materials to increase acceptability |
| Promotion of self-management | • Reduce barriers for patients to receive and adhere to medications and to implement lifestyle modification |
| Patient reminder systems (for follow-up appointments, BP checks, and self-management) | • Postcards, calls, texts, or emails to patients  
• Telehealth-delivered reminders |
| System change | • Standardization of BP measurement using an automated device and standardized protocol  
• Screening to identify all patients eligible for hypertension management  
• Systematic follow-up of patients for the initiation and intensification of antihypertensive therapy  
• Decision support to providers to guide protocol-based treatment decisions  
• Physician or other clinical champion designated to lead hypertension care improvement initiatives  
• Hypertension specialist available for consult  
• Partner with community resources to support BP management |

BP indicates blood pressure.

Data Supplement H. Responsibilities and Roles of the Hypertension Team

### Hypertension Team Responsibilities

- Communication and care coordination among various team members, the patient and family members or other support persons.
- Effective use of evidence-based diagnosis and management guidelines
- Regular, structured follow-up mechanisms and reminder systems to monitor patient progress
- Engage patients in their care by shared decision making
- Medication adherence support and appropriate education about hypertension medication
- Medication addition and titration using evidence-based treatment algorithms
- Use of evidence-based tools and resources designed to maximize self-management (including health behavior change, lifestyle modification, etc.)
- Follow a single, personalized plan of care based upon patient characteristics and needs

### Individual Hypertension Team Members

<table>
<thead>
<tr>
<th>Member Description</th>

## Data Supplement J. Publicly Available Performance Measures Used to Assess Hypertension Care Quality Services (363-367)

<table>
<thead>
<tr>
<th>Quality Measure</th>
<th>Source</th>
<th>Description</th>
<th>Additional information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Controlling High BP</td>
<td>NCQA</td>
<td>Percentage of patients 18–85 y of age who had a diagnosis of hypertension and whose BP was adequately controlled (&lt;140/90 mm Hg during the measurement period)</td>
<td>Used in the CMS, PQRS, MSSP, Medicare Advantage “Stars” ratings; component of Commercial Health Plan HEDIS quality measure set</td>
</tr>
</tbody>
</table>
| Comprehensive Diabetes Care: BP Control (<140/90 mm Hg) | NCQA | The percentage of patients 18–75 y of age with DM (type 1 and type 2) whose most recent BP level taken during the measurement y is <140/90 mm Hg | Used for:  
  - Accreditation  
  - Decision-making by businesses about health plan purchasing  
  - Decision-making by consumers about health plan/provider choice  
  - External oversight/Medicaid  
  - External oversight/Medicare  
  - External oversight/State government program  
  - Internal quality improvement  
  - Public reporting |
| Adult Kidney Disease: BP Management | PCPI, RPA | Percentage of patient visits for those patients ≥18 y of age with a diagnosis of CKD (stage 3, 4, or 5, not receiving renal replacement therapy) with a BP<140/90 mm Hg OR ≥140/90 mm Hg with a documented plan of care | Used in PQRS |
| Percentage of patients ≥18 y of age with BP documented in the medical record (every 2 y if <120/80 mm Hg, every y if 120–139/80–89 mm Hg) | ICSI | This measure is used to assess the percentage of patients age 18 y of age and older with BP documented in the medical record (every 2 y if <120/80 mm Hg, every y if 120–139/80–89 mm Hg) | Used for internal quality improvement |
| Controlling High BP for People with Serious Mental Illness | NCQA | The percentage of patients 18–85 y of age with serious mental illness who had a diagnosis of hypertension and whose BP was adequately controlled during the measurement | Current Use:  
  - Accreditation  
  - Decision-making by businesses about health plan purchasing  
  - Decision-making by consumers about health plan/provider choice  
  - External oversight/Medicaid  
  - External oversight/state government program | internal quality improvement |
| Diabetes Care for People with Serious Mental Illness: BP Control (<140/90 mm Hg) | NCQA | The percentage of patients 18–75 y of age with a serious mental illness and DM (type 1 and type 2) whose most recent BP reading during the measurement year is <140/90 mm Hg | Current Use:  
  - Accreditation  
  - Decision-making by businesses about health plan purchasing  
  - Decision-making by consumers about health plan/provider choice  
  - External oversight/Medicaid |
<table>
<thead>
<tr>
<th>Quality Measure</th>
<th>Source</th>
<th>Description</th>
<th>Additional information</th>
</tr>
</thead>
</table>
| Hypertension diagnosis and treatment: percentage of adult patients ≥18 y of age | ICSI         | Used to assess the percentage adult patients ≥18 y of age diagnosed with hypertension who are not at goal for hypertension and have received counseling on diet and physical activity in the past 12 mo | • External oversight/state government program  
• Internal quality improvement                                                             |
| Ambulatory care sensitive conditions: age-standardized acute care hospitalization | CIHI         | Used to assess the age-standardized acute care hospitalization rate for conditions where appropriate ambulatory care prevents or reduces the need for admission to the hospital per 100,000 population <75 y of age | Used for:  
• Monitoring health state(s)  
• National health policymaking  
• National reporting  
• State/Provincial health policymaking                                                  |
| Hypertension: the relative resource use by members with hypertension during the   | NCQA         | Used to assess the relative resource use by members with hypertension by reporting total standard cost and service frequency for all services for which the organization has paid or expects to pay during the measurement y | Used for:  
• Accreditation  
• External oversight/Medicaid  
• External oversight/Medicare  
• External oversight/State government program
